23

24 **ABSTRACT** The first stable isotope dilution assay for the determination of enniatins  
25 A, A1, B, B1 and beauvericin was developed. The [<sup>15</sup>N]<sub>3</sub>-labeled enniatins and  
26 beauvericin were biosynthesized by feeding two *Fusarium* strains with Na<sup>15</sup>NO<sub>3</sub> and  
27 subsequently isolated from the fungal culture. The chemical structures of the  
28 biosynthesized products were characterized by LC-MS/MS and <sup>1</sup>H-NMR. Standard  
29 solutions of [<sup>15</sup>N]<sub>3</sub>-labeled beauvericin, enniatin A, and enniatin A1 were accurately  
30 quantitated by quantitative NMR. Based on the use of the labeled products as  
31 internal standards, stable isotope dilution assays were developed and applied to  
32 various food samples using LC-MS/MS. The sample extracts were directly injected  
33 without any tedious cleanup procedures. The limits of detection were 3.9, 2.6, 3.7,  
34 1.9, and 4.4 µg/kg for enniatins A, A1, B, B1, and beauvericin, respectively. Limits of  
35 quantitation were 11.5 (enniatin A), 7.6 (enniatin A1), 10.9 (enniatin B), 5.8 (enniatin  
36 B1), and 13.1 µg/kg (beauvericin). Recoveries were within the range between 90-  
37 120%, and good intra-day and inter-day precision with coefficients of variation  
38 between 1.35-8.61% was obtained. Thus the stable isotope dilution assay presented  
39 here is similarly sensitive and precise, but more accurate than assays reported  
40 before. Analyses of cereals and cereal products revealed frequent contaminations of  
41 barley, wheat, rye, and oats with enniatins B and B1, whereas beauvericin was not  
42 quantifiable.

## 50 INTRODUCTION

51 Enniatins and beauvericin are cyclodepsipeptides consisting of three alternating D- $\alpha$ -  
52 hydroxyisovaleryl and *N*-methylamino acid units. They differ in the amino acid units in  
53 that beauvericin contains three phenylalanine residues, enniatins A and B each  
54 contains three isoleucine or valine residues, whereas enniatins A1 and B1 contain  
55 mixtures of these two.<sup>1-3</sup> Their structures are presented in **Figure 1**.

56 Enniatins and beauvericin are produced by various *Fusarium* species worldwide<sup>4,5</sup>  
57 with *Fusarium tricinctum* and *Fusarium avenaceum* being the most prevalent ones.

58 These toxins are gaining increasing attention due to their diverse biological activities.

59 Enniatins and beauvericin are known to be toxic to brine shrimp<sup>1,6</sup> and insects.<sup>7</sup>

60 Recently, their cytotoxicity on different cell lines of human origin has been reported<sup>8,9</sup>  
61 and they were shown to be phytotoxic<sup>10</sup> and exert antifungal activity.<sup>10</sup>

62 Different methods for determination of enniatins and beauvericin have been reported,  
63 among which HPLC with UV or MS detection are the most often used. As the  
64 maximum absorption of enniatins and beauvericin occurs at low wavelengths, UV  
65 detection is usually carried out between 192-209 nm,<sup>12,13</sup> which makes it easily  
66 affected by coeluting compounds. In contrast to this, HPLC coupled with MS or  
67 MS/MS detection proved to be more specific and sensitive, thus a number of  
68 methods were developed using different MS interfaces such as ESI and APCI.<sup>14-18</sup>

69 However, for quantitative methods based on LC-MS/MS, one issue that must be  
70 addressed is matrix effects. The latter may either decrease (ion suppression) or  
71 increase (ion enhancement) the intensity of analyte ions and therefore, affect the  
72 accuracy and reproducibility of the assay. Stable isotope dilution assays offer an ideal  
73 solution to overcome matrix effects, since the labeled internal standard and the  
74 analyte possess identical chemical and physical properties. Therefore, both are  
75 affected identically by matrix effects. In addition, analyte losses during sample

76 preparation also are compensated for by the use of these ideal internal standards.<sup>19</sup>  
77 However, no isotope labeled standards of enniatins and beauvericin are available,  
78 therefore, it is the aim of this study to synthesize labeled enniatins and beauvericin  
79 and to develop stable isotope dilution assays for these mycotoxins in a series of food  
80 samples. Whereas other isotope labeled *Fusarium* toxins such as [<sup>13</sup>C]-labeled type  
81 A trichothecenes have been prepared by chemical syntheses,<sup>20</sup> we here intended to  
82 prepare the depsipeptides by fungal biosyntheses.

83

84

## 85 **MATERIALS AND METHODS**

86

### 87 **Chemicals and Reagents**

88 Acetonitrile (MeCN), methanol, potassium chloride, citric acid, Iron(II) sulfate  
89 heptahydrate, ammonium sulfate, copper(II) sulfate pentahydrate, and glucose were  
90 purchased from Merck (Darmstadt, Germany). Potassium dihydrogen phosphate,  
91 zinc sulfate monohydrate, manganese(II) sulfate monohydrate, sodium molybdate  
92 dihydrate, and sodium nitrate were purchased from Sigma-Aldrich (Steinheim,  
93 Germany). The following compounds were obtained from the sources given in  
94 parentheses: magnesium sulfate heptahydrate (AppliChem, Darmstadt, Germany),  
95 boric acid (Avantor Performance Materials, Deventer, Netherlands), <sup>15</sup>N-sodium  
96 nitrate (98 atom% <sup>15</sup>N) (Cambridge Isotope Laboratories, MA, USA), beauvericin  
97 (AnaSpec, San Jose, USA), enniatin B (Bioaustralis, New South Wales, Australia),  
98 enniatins A, A1, B1 (Enzo Life Sciences, Lörrach, Germany ).

99

### 100 **Fungal culture**

101 Czapek-Dox liquid minimal medium,<sup>21</sup> with the normal NaNO<sub>3</sub> replaced by Na<sup>15</sup>NO<sub>3</sub>,  
102 sucrose replaced by glucose, and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> eliminated, was used as culture  
103 medium. Five 250 mL Erlenmeyer flasks, each containing 100 mL of the modified  
104 Czapek-Dox minimal medium were autoclaved at 121 °C for 25 min. An enniatins-  
105 producer *Fusarium sambucinum* strain 4.0979 previously grown on a synthetic agar  
106 low in nutrients (Synthetischer Nährstoffarmer Agar, SNA) was transferred to the five  
107 flasks, and incubated on a shaker (128 rpm) at 25 °C for 7 d. A beauvericin-producer  
108 *Fusarium fujikuroi* strain 4.0860 was cultured likewise to produce beauvericin. The  
109 *Fusarium* strains were obtained from Prof. Ludwig Niessen, Chair of Technical  
110 Microbiology, Technische Universität München.

111

#### 112 **Extraction of [<sup>15</sup>N]<sub>3</sub>-labeled enniatins and beauvericin**

113 The culture broth was centrifuged at 4000 rpm for 10 min, and the supernatant was  
114 discarded as the content of the target compounds was negligible. The residue, i.e.  
115 the harvested mycelia were dried in an oven at 50 °C for 18 h, and extracted with  
116 100 mL of MeCN-H<sub>2</sub>O (84:16, v/v) in an ultrasonic bath (Bandelin Sonorex Super RX  
117 106, Berlin, Germany) for 3 x 15 min, followed by extraction on a shaker for 2 d. The  
118 extract was filtered through 597 ½ S&S folded paper filters (Schleicher & Schuell,  
119 Dassel, Germany). The filtrate was then processed according to Song et al.<sup>22</sup> with  
120 minor modifications. Namely, the filtrate was defatted twice with 200 mL of hexane,  
121 and the bottom layer was evaporated to dryness, the residue was dissolved in 200  
122 mL of MeOH-H<sub>2</sub>O (55:45, v/v) and extracted twice with 200 mL of CH<sub>2</sub>Cl<sub>2</sub>. Then the  
123 CH<sub>2</sub>Cl<sub>2</sub> phase was evaporated and the residue was dissolved in 5 mL of methanol.  
124 This solution was passed through Strata C-18-T (55 µm, 140A, 1000 mg/6mL,  
125 Phenomenex, Torrance, CA, USA) SPE cartridges. The cartridges were eluted with  
126 methanol, then the eluate was collected and concentrated to 2 mL, and filtered

127 through a membrane filter (Spartan 13/0.45 RC, Whatman, Dassel, Germany) prior to  
128 HPLC.

129

### 130 **Preparation of [<sup>15</sup>N]<sub>3</sub>-labeled enniatins and beauvericin by HPLC**

131 HPLC analyses and preparations were performed using an analytical Merck Hitachi  
132 system (Tokyo, Japan) including an L-7455 diode array detector, an L-7200

133 autosampler, a D-7000 interface, and an L-7100 pump. A 250 mm x 3.0 mm i.d., 4  
134 μm, Synergi Hydro-RP 80A (Phenomenex, Torrance, CA, USA) column was used.

135 HPLC conditions were set up using a constant flow of 0.6 mL/min and a very shallow  
136 gradient elution started with MeCN-H<sub>2</sub>O (65:35, v/v), kept for 5 min and linearly

137 increased to 68% MeCN in 10 min, maintained for 12 min before switched back to  
138 the starting condition in 3 min. The enniatins and beauvericin were detected at 203

139 nm. Using these conditions, nine fractions were eluted and collected separately.

140 Each fraction was subjected to LC-MS/MS analysis, fractions 1, 3, and 6 showed  
141 similar fragmentation pattern and retention time with that of enniatin B, enniatin B1,

142 and enniatin A1 standards, respectively. Both fraction 8 and 9 showed similar

143 fragmentation with that of enniatin A standard. In subsequent <sup>1</sup>H-NMR tests, peak 9

144 was confirmed to be enniatin A, whereas peak 8 remains unknown. The HPLC

145 separation was then repeated and the five fractions were collected and pooled. Each

146 pooled fraction was evaporated to dryness under reduced pressure and redissolved  
147 in 180 μL of methanol.

148 To further purify the five fractions, a second run of HPLC separation using the same  
149 system mentioned above was performed for each of them separately. Only the

150 mobile phase was different, the flow was kept constant at 0.6 mL/min, MeOH-H<sub>2</sub>O

151 (78:22, v/v) was used as starting eluent, maintained for 5 min before rising to 92%

152 MeOH over 20 min, then kept for 1 min, and taken back to starting ratio in 4 min.

153 Each rechromatographed fraction was coinjected with pure standard for confirmation,  
154 and their purity was further verified by LC-MS in the full scan mode as described  
155 below. According to the results of quantitative NMR described below the yields for  
156 [<sup>15</sup>N]<sub>3</sub>-labeled enniatin A, [<sup>15</sup>N]<sub>3</sub>-labeled enniatin A1, and [<sup>15</sup>N]<sub>3</sub>-labeled beauvericin  
157 were 430 μg, 450 μg, and 1460 mg, respectively,

158

### 159 <sup>1</sup>H-NMR

160 The structures of purified compounds were characterized by <sup>1</sup>H-NMR on a Bruker AV  
161 III system (Bruker Rheinstetten, Germany) operating at a frequency of 500.13 MHz.

162 All five compounds were dissolved in CDCl<sub>3</sub>.

163 The <sup>1</sup>H-NMR chemical shifts for beauvericin, given in δ/ppm (TMS) are: 7.16 (m,  
164 15H, aromatic H, Phe), 5.47 (m, 3H, αH, Phe), 4.80 (d, *J* = 8.1 Hz, 3H, αH,  
165 hydroxyisovaleryl), 3.32 (m, 3H, βH, Phe), 2.95 (s, 9H, N-CH<sub>3</sub>), 2.89 (m, 3H, βH,  
166 Phe), 1.89 (m, 3H, βH, hydroxyisovaleryl), 0.73 (d, *J* = 6.6 Hz, 9H, γ(CH<sub>3</sub>),  
167 hydroxyisovaleryl), 0.34 (d, *J* = 6.8 Hz, 9H, γ(CH<sub>3</sub>), hydroxyisovaleryl). The <sup>1</sup>H-NMR  
168 chemical shifts for enniatins are listed in **Table 1**. The data are in good agreement  
169 with that from literature.<sup>1-3</sup>

170

### 171 Quantitative NMR

172 The method of quantitative NMR for [<sup>15</sup>N]<sub>3</sub>-labeled beauvericin, enniatin A and  
173 enniatin A1 was similar to that described by Korn et al.<sup>24</sup> Briefly, the purified  
174 compounds were dissolved in 600 μL of methanol-d<sub>3</sub> (Euriso-top, Gif sur Yvette  
175 Cedex, France), and analysed in 5 x 178 mm NMR tubes (Norell, ST500-7,  
176 Landisville, USA). A caffeine sample of known concentration was used as external  
177 standard. For quantitation, the signals at 7.87 ppm (caffeine), 5.47 ppm ([<sup>15</sup>N]<sub>3</sub>-

178 labeled beauvericin), 5.14 ppm ( $[^{15}\text{N}]_3$ -labeled enniatin A), and 5.09 ppm ( $[^{15}\text{N}]_3$ -  
179 labeled enniatin A1) were chosen. Intensity of the signal was integrated manually.

180

### 181 **LC-MS and LC-MS/MS**

182 Liquid chromatography was carried out on a Shimadzu LC-20A Prominence system  
183 (Shimadzu, Kyoto, Japan) using a 150 mm x 2.0 mm i.d., 4  $\mu\text{m}$ , Synergi Polar RP  
184 80A column (Phenomenex, Torrance, CA, USA). The starting mobile phase MeCN-  
185  $\text{H}_2\text{O}$  (65:35, v/v) was kept constant for 5 min and linearly raised to 75% MeCN in 7  
186 min. After 1 min at 75% MeCN, the gradient was increased to 100% MeCN in 2 min,  
187 and held for 1 min before returning to the starting condition in 3 min. Injection volume  
188 was 10  $\mu\text{L}$ , flow rate was 0.2 mL/min, and equilibration time between two runs was 5  
189 min. Data acquisition was carried out using Analyst 1.5 software (Applied Biosystems  
190 Inc., Foster City, CA, USA).

191 The LC was interfaced to a hybrid triple quadrupole/linear ion trap mass  
192 spectrometer (API 4000 QTrap; Applied Biosystems Inc., Foster City, CA, USA)  
193 operated in the positive ESI mode. The ion source parameters were set as follows:  
194 curtain gas, 10 psi; temperature, 450  $^\circ\text{C}$ ; ion source gas 1, 45 psi; ion source gas 2,  
195 50 psi; ion spray voltage, 5500 V. MS parameters were optimized by direct infusion  
196 of each standard solution (40 ng/mL) into the source.

197 Full scan spectra for confirmation of the purified compounds were recorded in a mass  
198 range from  $m/z$  200 to 1500 and a scan time of 1.0 s.

199 For MS/MS measurements, the mass spectrometer was operated in the MRM  
200 (multiple reaction monitoring) mode, a valve was used to divert the column effluent to  
201 the mass spectrometer from 5 to 13.5 min and to waste for the rest of the run.

202

### 203 **Preparation of standard solutions**

204 All standard solutions were prepared in methanol. The concentration of labeled  
205 enniatin A, enniatin A1 and beauvericin were determined by quantitative NMR  
206 described above, stock solutions of 100 µg/mL of each compound was prepared  
207 accordingly, from which further dilutions of 10 µg/mL were prepared. The UV  
208 absorptions of the 10 µg/mL enniatin A and enniatin A1 were determined on a UV  
209 spectrometer Specord 50 (Analytik Jena, Jena, Germany) at the maximum  
210 absorption wavelength of 203 nm in triplicates. The ratio between the molar  
211 extinction coefficients of enniatin A and enniatin A1 was calculated from the mean of  
212 the triplicates, and the result was 1.007, which confirmed the assumption that the  
213 molar extinction coefficients of enniatins A, A1, B, and B1 are all the same since they  
214 differ only in the side chains which are devoid of UV chromophores. Based on this  
215 notion, the concentrations of enniatin B and enniatin B1 were determined by  
216 comparing their UV absorptions at 203 nm to those of enniatin A and enniatin A1.  
217 Stock solutions of 100 µg/mL were prepared for labeled enniatin B and enniatin B1,  
218 as well as unlabeled enniatins and beauvericin. Further dilutions of 1 µg/mL, 100  
219 ng/mL, and 10 ng/mL were also prepared. All solutions were stored in the dark at 4  
220 °C.

221

## 222 **Sample preparation**

223 Food samples were purchased from local retail stores except from barley malts,  
224 which were obtained from Bavarian malt producers. All samples were ground (Ika  
225 Universalmühler M20, Staufen, Germany) into fine powder before extraction. 1 g of  
226 each dried sample was spiked with 10 ng (100 µL x 100 ng/mL solution in MeCN) of  
227 each of the labeled standards, after the solvent was evaporated, the sample was  
228 suspended in 10 mL of MeCN-H<sub>2</sub>O (84:16, v/v), vortexed (Ika Vortex Genius 3,  
229 Staufen, Germany) for 1 min and extracted for 1.5 h, after which each sample was

230 centrifuged at 4000 rpm for 10 min, and 1 mL of the supernatant was filtered through  
231 a membrane filter (Spartan 13/0.45 RC, Whatman, Dassel, Germany) prior to HPLC.

232

### 233 **Calibration and quantitation**

234 Constant amounts (10 ng) of labeled standard (S) were mixed with varying amounts  
235 of analyte (A) in molar ratios between 0.1 to 10 (1:10, 1:5, 1:2, 1:1, 2:1, 5:1, 10:1).  
236 After LC-MS/MS measurement, response curves were obtained from molar ratios  
237  $[n(A)/n(S)]$  versus peak area ratios  $[A(A)/A(S)]$ , and response functions were  
238 obtained using linear regression. The response functions were as follows  $[y =$   
239  $n(A)/n(S), x = A(A)/A(S)]$ : enniatin A,  $y = 1,8692x - 0,0406$  ( $R^2 = 0.9975$ ); enniatin A1,  
240  $y = 1,4310x - 0,0821$  ( $R^2 = 0.9984$ ); enniatin B,  $y = 1,5138x - 0,0674$  ( $R^2 = 0.9958$ );  
241 enniatin B1,  $y = 1,7618x - 0,1002$  ( $R^2 = 0.9919$ ); beauvericin,  $y = 0,9042x - 0,1627$  ( $R^2 =$   
242  $0.9971$ ). According to the Mandel test, all functions were linear within the chosen  
243 molar ratios (0.1-10). Residual plots were drawn to examine the appropriateness of  
244 using linear regression, and all five plots showed random patterns. The contents of  
245 enniatins and beauvericin in samples were calculated using the respective response  
246 functions.

247

### 248 **Limits of detection (LODs) and quantitation (LOQs)**

249 LODs and LOQs were calculated according to the procedures suggested by  
250 Vogelgesang and Hädrich.<sup>23</sup> A potato starch devoid of enniatins and beauvericin was  
251 used as blank for the determination of LODs and LOQs. The blank was spiked with  
252 enniatins and beauvericin at four different amounts (5, 20, 35, and 50  $\mu\text{g}/\text{kg}$ ), each in  
253 triplicate. The samples were extracted and analyzed as described before.

254

### 255 **Precision**

256 Intra-day (n = 5) and inter-day (n = 3) precision was determined within 6 weeks. As  
257 no single sample that contained all four enniatins as well as beauvericin was found  
258 by that time, precision was determined with three samples: a naturally contaminated  
259 whole wheat flour sample was used to measure enniatins A1, B and B1, a naturally  
260 contaminated wheat grain sample was used for enniatin A, and a rice sample that  
261 contained none of these mycotoxins was spiked with 45 µg/kg of beauvericin for  
262 determination since no naturally contaminated beauvericin sample was available.

263

#### 264 **Recovery**

265 Blank samples (potato starch) were spiked in triplicate with different amounts (20, 35,  
266 and 50 µg/kg) of enniatins and beauvericin, and analyzed as described before.

267 Recovery was calculated as the mean of the spiking experiments.

268

269

## 270 **RESULTS AND DISCUSSION**

271

### 272 **Biosynthesis of [<sup>15</sup>N]<sub>3</sub>-labeled enniatins and beauvericin**

273 Synthesis of the [<sup>15</sup>N]<sub>3</sub>-labeled enniatins and beauvericin was achieved by cultivating  
274 the enniatins/beauvericin-producing *Fusarium* strains separately in a synthetic  
275 medium, Czapek-Dox liquid minimal medium, with modification. To make sure that  
276 the Na<sup>15</sup>NO<sub>3</sub> was the only nitrogen source for the fungi, the unlabeled NaNO<sub>3</sub> was  
277 replaced by labeled one, and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> which is only a trace element of the medium  
278 was eliminated. The lack of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in the medium was proved to have no  
279 significant influence on the production of enniatins and beauvericin in a previous  
280 experiment (not reported). The two enniatins/beauvericin-producing strains were  
281 screened from 54 *Fusarium* strains (4 species: *F. fujikuroi*, *F. oxysporum*, *F.*

282 *proliferatum*, and *F. sambucinum*) before feeding them with labeled nitrogen. To the  
283 best of our knowledge, this is the first literature report on the production of  
284 mycotoxins labeled with the nitrogen isotope  $^{15}\text{N}$ . Up to now, similar protocols were  
285 only applied to produce fungal peptides from  $\text{K}^{15}\text{NO}_3$  or chitin from  $(^{15}\text{NH}_4)_2\text{SO}_4$ .<sup>28,29</sup>  
286

### 287 **Quantitative NMR**

288 Determining the concentration of standard solutions of labeled enniatins and  
289 beauvericin is inaccurate by gravimetry due to the small amount of the mycotoxins  
290 isolated from fungal culture. The precise amount of commercially bought unlabeled  
291 enniatins and beauvericin was also unknown as the purity is not certified. Thus,  
292 quantitative NMR was adopted, which revealed the molar concentration of the three  
293 mycotoxins as follows: 1.0355 mmol/L ( $[^{15}\text{N}]_3$ -labeled enniatin A), 1.1203 mmol/L  
294 ( $[^{15}\text{N}]_3$ -labeled enniatin A1), 3.1019 mmol/L ( $[^{15}\text{N}]_3$ -labeled beauvericin). As already  
295 reported for the ochratoxin A,<sup>24</sup> quantitative NMR proved again to be a suitable and  
296 accurate tool in mycotoxin quantitation.

297

### 298 **LC-MS/MS**

299 Detection of the analytes was carried out by ESI-(+)-MS/MS, product ion scans of  
300 enniatins and beauvericin standards were recorded using the protonated molecules  
301 as precursor ions. Generally, the labeled standards gave similar fragmentation  
302 patterns to the respective unlabeled compounds. As displayed in **Figure 2**, the three  
303 most intense fragments derived from  $[\text{M}+\text{H}]^+$  ion ( $m/z$  668) of unlabeled enniatin A1  
304 were  $m/z$  196,  $m/z$  210, and  $m/z$  228, similar fragments were produced by  $[\text{M}+\text{H}]^+$   
305 ions ( $m/z$  671) of labeled enniatin A1, with  $m/z$  197,  $m/z$  211, and  $m/z$  229 being the  
306 three most intense signals. The fragmentation of labeled and unlabeled beauvericin  
307 is shown in **Figure 3**. Whereas the protonated molecules contained a mass

308 increment of three being in accordance with the three [<sup>15</sup>N] incorporated, the  
309 fragments contained only a mass increment of one equivalent to one [<sup>15</sup>N]  
310 incorporated. Based on this information, a fragmentation pathway of enniatins and  
311 beauvericin is proposed, with the protonated molecule in the center of **Figure 4**  
312 showing an imaginary molecule composed of all side chains incorporated in the  
313 different enniatins and beauvericin. In accordance with the observed occurrence of  
314 one labeled nitrogen in each fragment, the fragments obviously contained one amino  
315 acid moiety. Hypothetically, the ring of the molecule had an even chance to break in  
316 either of the three marked C-O bonds. Due to the different substituents on the amino  
317 acid residues, enniatins and beauvericin resulted in different fragments. For  
318 beauvericin, most plausible were the fragments containing phenylalanine residues  
319 (*m/z* 262), which then lost H<sub>2</sub>O to give *m/z* 244. For enniatin A, fragments of *m/z* 228  
320 containing *sec*-butyl moieties were formed after break of the ring, and subsequent  
321 loss of H<sub>2</sub>O resulted in *m/z* 210. Similarly, fragments of *m/z* 214 and *m/z* 196 were  
322 obtained from enniatin B. For enniatin A1 and B1 containing both isopropyl and *sec*-  
323 butyl side chains, a mixture of *m/z* 196, *m/z* 214, *m/z* 210, and *m/z* 228 fragments  
324 was observed.

325 In previous studies, MS/MS fragmentations of enniatins and beauvericin were  
326 reported but neither explained in detail nor substantiated.

327 In their LC-MS/MS method, Sørensen et al.<sup>14</sup> used the fragments at *m/z* 555 as well  
328 as 210, at *m/z* 541 as well as 210, at *m/z* 527 as well as 196, at *m/z* 228 as well as  
329 196 and at *m/z* 362 as well as 244 for enniatin A, enniatin A1, enniatin B, enniatin B1  
330 and beauvericin, respectively. The masses of the quantifier ions (*m/z* 210, 196, 244)  
331 were assigned to protonated “monomers” with phenylmethyl, *sec*-butyl or isopropyl  
332 residues after loss of water without giving any detailed structural suggestions for the  
333 fragments. The same fragments were reported by Jestoi et al.<sup>17</sup>, who did not

334 comment on their structure or on the route of formation. In another report, Sewram et  
335 al.<sup>15</sup> explained that the fragments of beauvericin resulted from the cleavage of the  
336 amide bond, which we could not confirm in our studies.

337

### 338 **Calibration and quantitation**

339 Calibration curves were obtained by linear regression, showing good linearity within  
340 the chosen molar ratios (0.1-10) confirmed by the Mandel test. The response factors  
341 for enniatins were all above 1.4 and exceeded the usual response factors around 1.0  
342 for stable isotope dilution assays. This can be partly explained by the different  
343 isotope abundance between labeled and natural enniatins, as approximately 95.8-  
344 96.5% of the isotopologues in the biosynthesized labeled enniatins were M+3 ones,  
345 and the abundance of M isotopologues in unlabeled enniatins standards varied  
346 between 51.1%-62.5% due to natural isotopologues. According to this isotopologic  
347 distribution, large response factors between 1.53-1.88 would be expected, but as the  
348 signals of natural isotopologues in LC-MS/MS are reduced due to higher specificity,  
349 the found values between 1.43-1.87 are plausible. The isotope abundances for  
350 labeled and unlabeled enniatins and beauvericin were estimated by LC-MS full scan,  
351 in which the respective fragmentations of M, M+1, M+2, and M+3 of each compound  
352 were recorded and calculated. However, this cannot explain the normal response  
353 factor (0.9) but abnormally high y intercept (0.16) of beauvericin, since the M  
354 isotopologue abundance was 58.1% in unlabeled standard, and M+3 isotopologue  
355 abundance was 93.2% in labeled beauvericin. Based on the considerations detailed  
356 before, a response factor up to 1.60 would be expected. However, multiple and  
357 regular tests of the calibration curve confirmed these unusual values. Therefore,  
358 additional isotope effects have to be assumed.

359

## 360 **Limits of detection (LODs) and quantitation (LOQs)**

361 LODs and LOQs were calculated according to Vogelgesang and Hädrich,<sup>23</sup> which is  
362 based on a calibration curve obtained from spiking experiments in a matrix free from  
363 the respective analyte. As shown in **Table 2**, the LODs ranged from 1.9 to 4.4 µg/kg,  
364 and LOQs ranged from 5.8 to 13.1 µg/kg. Thus the stable isotope dilution assay  
365 presented here is two orders of magnitude more sensitive than methods previously  
366 reported<sup>13,26</sup> and five times more sensitive than that presented by Pamel et al.<sup>18</sup> The  
367 methods recently reported<sup>14,15</sup> are similarly sensitive as our assay. In contrast to this,  
368 two further LC-MS/MS assays were reported to be approximately ten times more  
369 sensitive. For the first one, Jestoi et al.<sup>17</sup> applied five times more sample weight and  
370 did not report how LOD was determined, and for the second one, Sewram et al.<sup>15</sup>  
371 used a twenty times higher sample weight than we did. Similarly to Jestoi et al.<sup>17</sup>, the  
372 deduction of LOD in food samples remains unclear in the latter report.

373

## 374 **Precision**

375 The inter-day (n = 3) and intra-day (n = 5) coefficients of variation are given in **Table**  
376 **2**, they varied between 1.35 and 8.61%. With these results the stable isotope dilution  
377 assay presented here was similarly precise as those methods reported by Mahnine  
378 et al.<sup>13</sup> In contrast to this, the method of Pamel et al.<sup>18</sup> revealed relative standard  
379 deviations ranging between 8 and 49 % and, therefore, was less precise.

380

## 381 **Recovery**

382 **Table 2** shows the recoveries determined with different spiking levels (20, 35, and 50  
383 µg/kg) of each mycotoxin. All the recoveries fell in the range between 90 and 120%,  
384 with low standard deviations. These recoveries confirmed the expected superiority of

385 stable isotope dilution assays over other assays as the other methods all showed  
386 recoveries for at least one depsipeptide as low as or far below 85%.<sup>14-18,26</sup>

387

### 388 **Analysis of cereals and relating food samples**

389 A series of cereals and related food samples were analyzed for enniatins and  
390 beauvericin contamination using the stable isotope dilution assays developed. The  
391 results were summarized in **Table 3**. **Figure 5** presents the LC-MS/MS  
392 chromatograms of a barley sample.

393 Overall, our findings show high incidence of particularly enniatin B and B1. Except for  
394 rice, all the samples analyzed contained at least one of the five mycotoxins. The  
395 percentages of samples contaminated with enniatins A, A1, B, B1 and BEA were  
396 16.9%, 52.3%, 87.7%, 83.1%, and 24.6%, respectively.

397 The occurrence and concentrations of enniatins were in a distinct ratio (enniatin B >  
398 enniatin B1 > enniatin A1 > enniatin A), which was in accordance with previous  
399 investigations on Norwegian grains and Danish maize.<sup>14,25</sup> Wheat grains and barley  
400 malts were the most severely contaminated with enniatins, indeed, the highest levels  
401 of all four enniatins were detected in barley malts, with the amount of enniatin B and  
402 B1 reached 6998 and 6762 µg/kg, respectively. The contents of enniatins in other  
403 food samples were significantly lower, ranging from not detectable to 735 µg/kg.  
404 Earlier studies have reported the presence of enniatins in a variety of food samples,  
405 including wheat, barley, oat, maize, and cereal based products with the levels of  
406 enniatins covered a wide range between below 3.0 µg/kg and 814 mg/kg.<sup>13-14, 25-</sup>  
407 <sup>26</sup>Therefore, our results of enniatins levels (from less than 5.8 µg/kg to 6998 µg/kg)  
408 fell within the range of previous reports, but the maximum level was considerably  
409 lower.

410 Interestingly, none of our samples contained beauvericin above limit of quantitation

411 (13.1 µg/kg), whereas other groups have reported cereals from Spain,<sup>26</sup> and Italy<sup>27</sup>  
412 with beauvericin levels up to 11.8, and 520 mg/kg, respectively.  
413 In addition, three sets of organic and conventional cereal products (wheat flour, oat  
414 flakes, and spaghetti) were compared for their contamination of enniatins and  
415 beauvericin. The organic products were found to be less contaminated with enniatins  
416 in average, their maximum levels were also lower. This result is similar to that for the  
417 trichothecene deoxynivalenol, which was found more abundantly in conventionally  
418 grown cereals.<sup>30</sup> The frequency of beauvericin in organic products was slightly higher  
419 than that in conventional ones, however, due to the negligibly low amount of  
420 beauvericin in all samples, this would not mean the organic products were a hazard  
421 to the consumer.

422

### 423 **Acknowledgement**

424 We thank Prof. Ludwig Niessen, Chair of Technical Microbiology, Technische  
425 Universität München, for providing us with the *Fusarium* strains.

426 Ling Hu would also like to thank Chinese Scholarship Council for financial support.

427

**Table 2.** Validation Data of the Stable Isotope Dilution Assay for Enniatins and Beauvericin

	LOD (µg/kg)	LOQ (µg/kg)	Coefficients of variation		Recovery (3 spiking levels)		
			Inter-day (n = 3)	Intra-day (n = 5)	20 µg/kg	35 µg/kg	50 µg/kg
Enniatin A	3.9	11.5	1.36%	1.35%	98 ± 7.6%	105 ± 3.4%	107 ± 7.2%
Enniatin A1	2.6	7.6	8.61%	6.31%	96 ± 2.6%	102 ± 4.8%	98 ± 2.2%
Enniatin B	3.7	10.9	5.58%	7.21%	99 ± 3.9%	100 ± 3.1%	106 ± 6.9%
Enniatin B1	1.9	5.8	4.09%	4.89%	105 ± 5.1%	100 ± 1.8%	104 ± 1.9%
Beauvericin	4.4	13.1	1.48%	1.41%	110 ± 3.4%	109 ± 1.0%	103 ± 8.6%

**Table 3.** Presence of Enniatins and Beauvericin in Analyzed Food Samples ( $\mu\text{g}/\text{kg}$ )

Samples <sup>a</sup>	Number	enniatin A			enniatin A1			enniatin B			enniatin B1			beauvericin	
		Positive samples	Min-max <sup>b</sup>	Mean <sup>c</sup>	Positive samples	Min-max <sup>b</sup>	Mean <sup>c</sup>	Positive samples	Min-max <sup>b</sup>	Mean <sup>c</sup>	Positive samples	Min-max <sup>b</sup>	Mean <sup>c</sup>	Positive samples	Min-max <sup>b</sup>
barley malts	6	5	52-448	220	6	24-2721	1225	6	196-6998	3668	6	138-6762	3624	2	nq
wheat grains	6	5	nq-38	17	6	33-232	111	6	508-2125	1306	6	210-1066	658	2	nq
oat grains (organic)	2	0	-	-	0	-	-	2	nq	5	2	nq	3	1	nq
rice grains	6	0	-	-	0	-	-	0	-	-	0	-	-	0	-
maize grains	2	0	-	-	0	-	-	2	nq	5	2	3-4	4	2	nq
maize grits (organic)	2	0	-	-	0	-	-	1	11	6	-	-	-	0	-
maize flour	1	0	-	-	0	-	-	1	nq	5	1	nq	3	1	nq
wheat bread	5	0	-	-	3	nq	3	5	17-90	47	5	7-35	21	0	-
rye bread	5	0	-	-	3	nq-23	8	5	25-735	263	5	9-256	88	0	-
wheat flour	5	1	7	3	4	7-45	15	5	41-332	125	5	13-217	75	0	-
wheat flour (organic)	5	0	-	-	4	nq-21	7	4	48-114	65	5	nq-74	33	1	nq
oat flakes	5	0	-	-	2	9-13	5	5	nq-94	42	4	nq-50	21	3	nq
oat flakes (organic)	5	0	-	-	0	-	-	5	nq-62	24	3	nq-21	9	4	nq
spaghetti	5	0	-	-	4	nq-12	5	5	22-642	234	5	6-134	54	0	-
spaghetti (organic)	5	0	-	-	2	nq	2	5	nq-68	25	5	nq-19	11	0	-

-, not detectable; nq, detected, but below limit of quantitation.

<sup>a</sup>The samples were conventional unless indicated as organic. <sup>b</sup>Min = minimum detected value; max = maximum detected value. <sup>c</sup>Mean = mean value of all samples in the category, with not detectable and not quantifiable results considered as  $nq = \frac{1}{2}(\text{LOQ} + \text{LOD})$ ,  $- = \frac{1}{2}(\text{LOD})$ .

## FIGURE LEGENDS

- Figure 1 Chemical structures of enniatins A, A1, B, B1 and beauvericin.
- Figure 2 (A) ESI-(+)-LC-MS/MS spectrum of enniatin A1 (precursor  $m/z = 668$ ,  $[M+H]^+$ ); (B) ESI-(+)-LC-MS/MS spectrum of  $[^{15}\text{N}]_3$ -labeled enniatin A1 (precursor  $m/z = 671$ ,  $[M+H]^+$ )
- Figure 3 (A) ESI-(+)-LC-MS/MS spectrum of beauvericin (precursor  $m/z = 784$ ,  $[M+H]^+$ ); (B) ESI-(+)-LC-MS/MS spectrum of  $[^{15}\text{N}]_3$ -labeled beauvericin (precursor  $m/z = 787$ ,  $[M+H]^+$ )
- Figure 4 Proposed MS/MS fragmentation routes of enniatins and beauvericin.  
The depicted structure refers to a hypothetical molecule composed of the amino acids included in enniatins and beauvericin.
- Figure 5 LC-MS/MS chromatograms of a barley malt sample: (A) analytes; (B)  $[^{15}\text{N}]_3$ -labeled standards

Figure 1

BEA:  $R_1=R_2=R_3=-\text{CH}_2\text{C}_6\text{H}_5$

ENN A:  $R_1=R_2=R_3=-\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}_3$

ENN A1:  $R_1=R_2=-\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}_3$ ,  $R_3=-\text{CH}(\text{CH}_3)_2$

ENN B:  $R_1=R_2=R_3=-\text{CH}(\text{CH}_3)_2$

ENN B1:  $R_1=R_2=-\text{CH}(\text{CH}_3)_2$ ,  $R_3=-\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}_3$
