38th IEW @IEA, Paris, June 5, 2019

Supported by:

Federal Ministry  
for Economic Affairs  
and Energy

on the basis of a decision  
by the German Bundestag

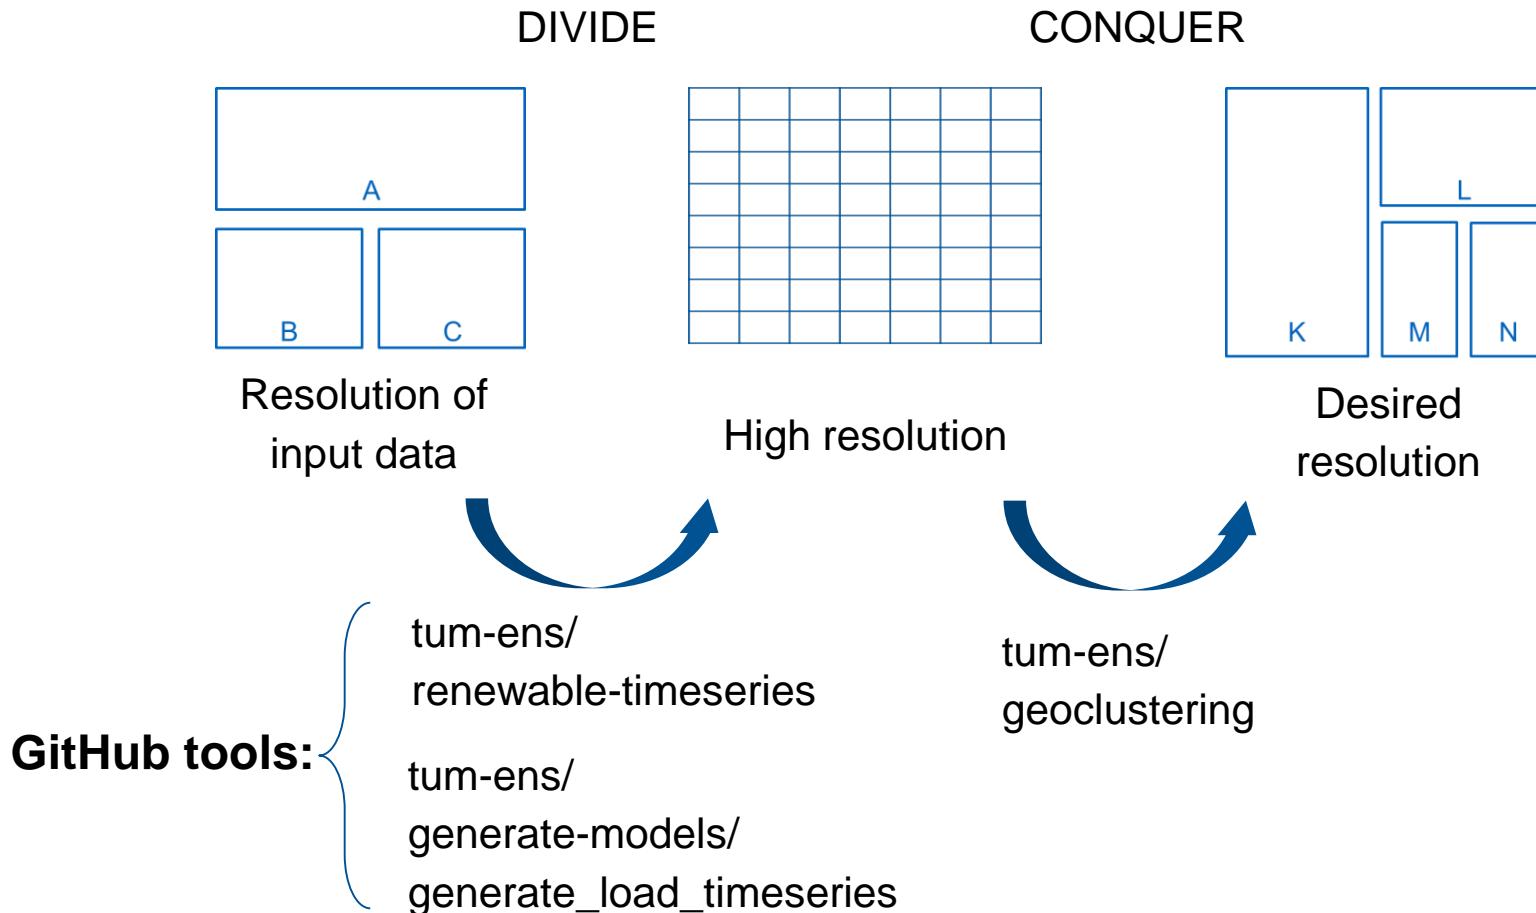

# Motivation

- Electricity system optimization models require information about the load, usually in the form of time series.
  - Such information is usually available on a country level or on a sub-national level (federal states, counties, or balancing areas of utilities).
  - However, this data resolution might not be adequate for research questions where the desired model region is different.
- Method to distribute the electric load spatially, while preserving the important characteristics for energy system models (total demand, profile shape, peak)?

# Proposed workflow

In the general case:

# How the tool works

**Shapefiles**

**Initial time series**

**Global maps:** land  
use and population

**param:** sectors,  
sector shares, sector  
to landuse matrix,  
typical load profiles

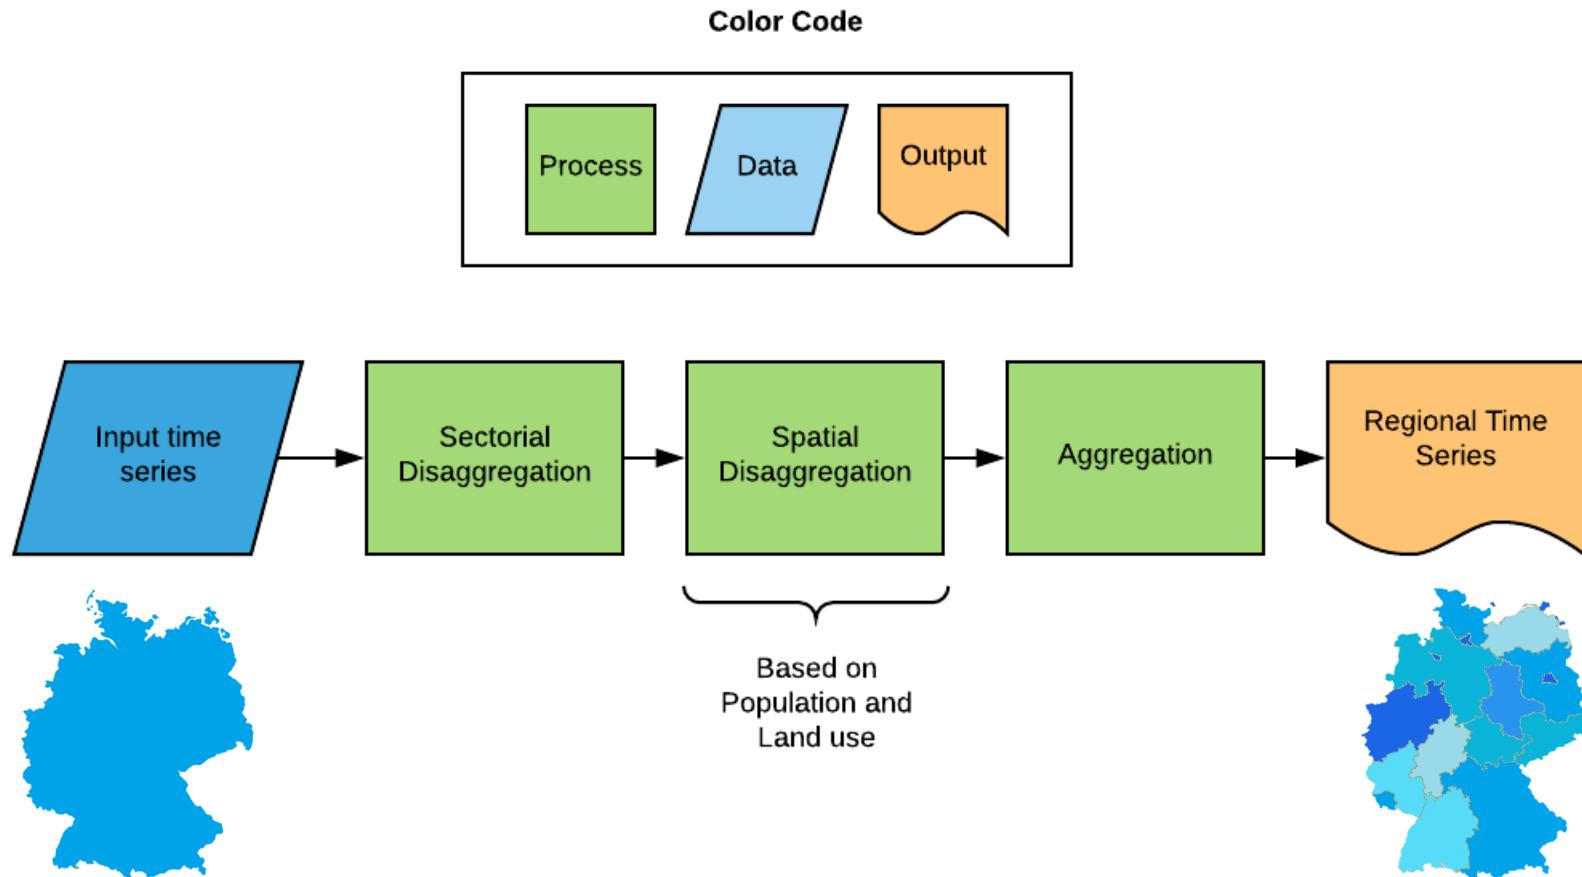

**paths:** to files saved  
locally

**GitHub:**  
**tum-ens/**  
**generate-models/**  
**generate\_load\_timeseries**

**Time series**

**Maps of demand  
distribution**

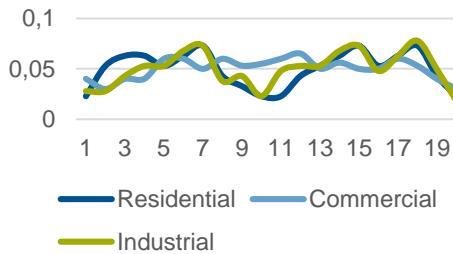

# generate\_load\_timeseries

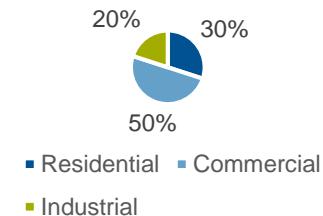

# generate\_load\_timeseries

## Sectorial disaggregation

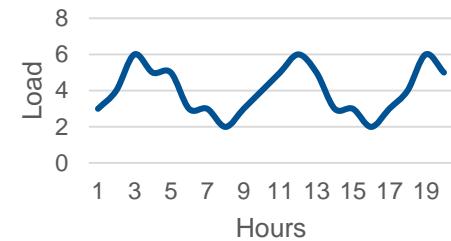

Typical load profiles

Sector Share

## Spatial disaggregation

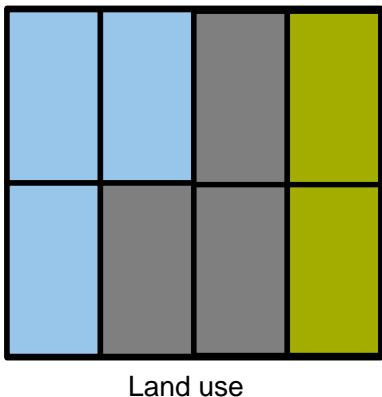

Raster

# generate\_load\_timeseries

## Spatial disaggregation

Raster

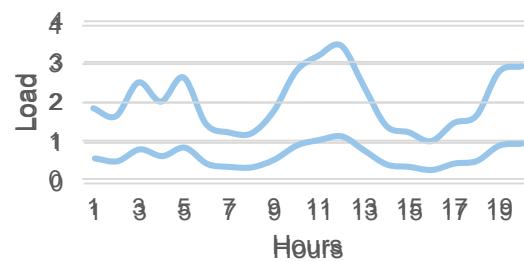

Assumptions

|                |   |
|----------------|---|
| Forest         | 2 |
| 30% Commercial |   |
| 70% Industrial |   |
| Urban          | 3 |
| 80% Commercial |   |
| 20% Industrial |   |
| Sea            | 3 |
| 0% Commercial  |   |
| 0% Agriculture |   |

$$\text{C. pixels} = 0.3 \times 2 + 0.8 \times 3 = 3$$

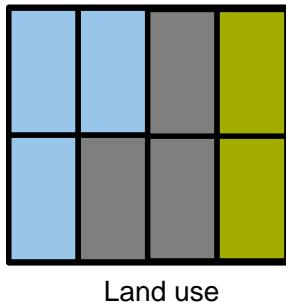

Commercial load per pixel

# generate\_load\_timeseries

## Spatial disaggregation

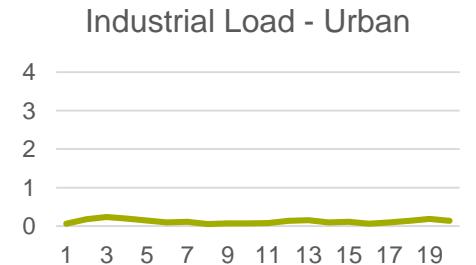

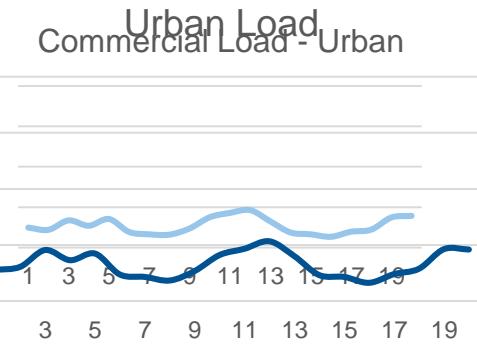

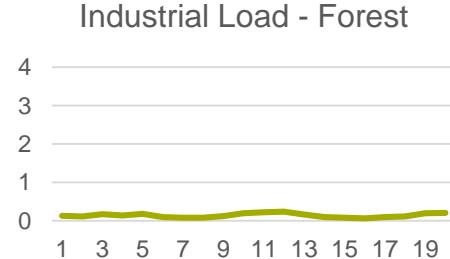

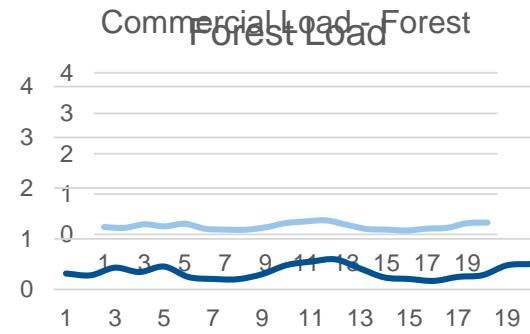

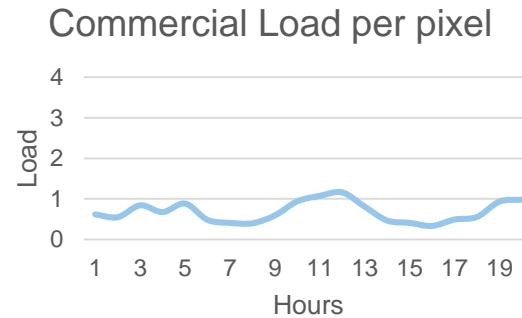

Raster

**Forest 2**  
30% Commercial  
70% Industrial

**Urban 3**  
80% Commercial  
20% Industrial

**Sea 3**  
0% Commercial  
0% Agriculture

# Validation

## Regions studied:

Norway

- 5 Bidding zones

Sweden

- 4 Bidding zones

Denmark

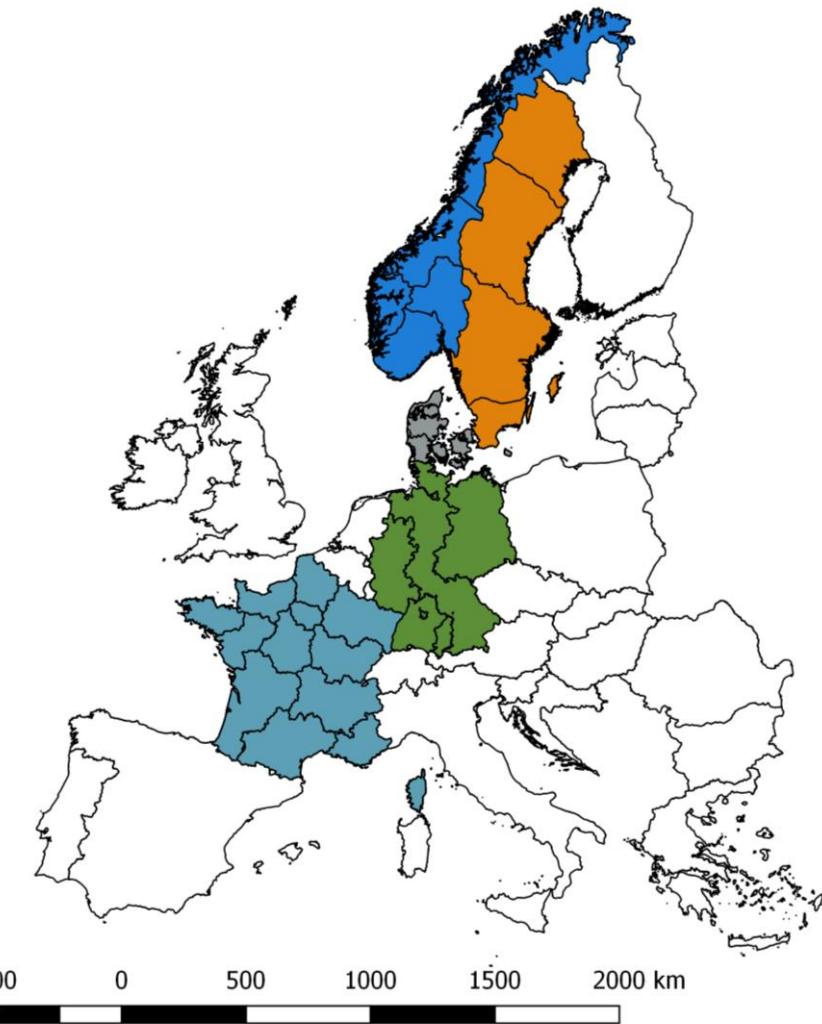

- 2 Bidding zones

Germany

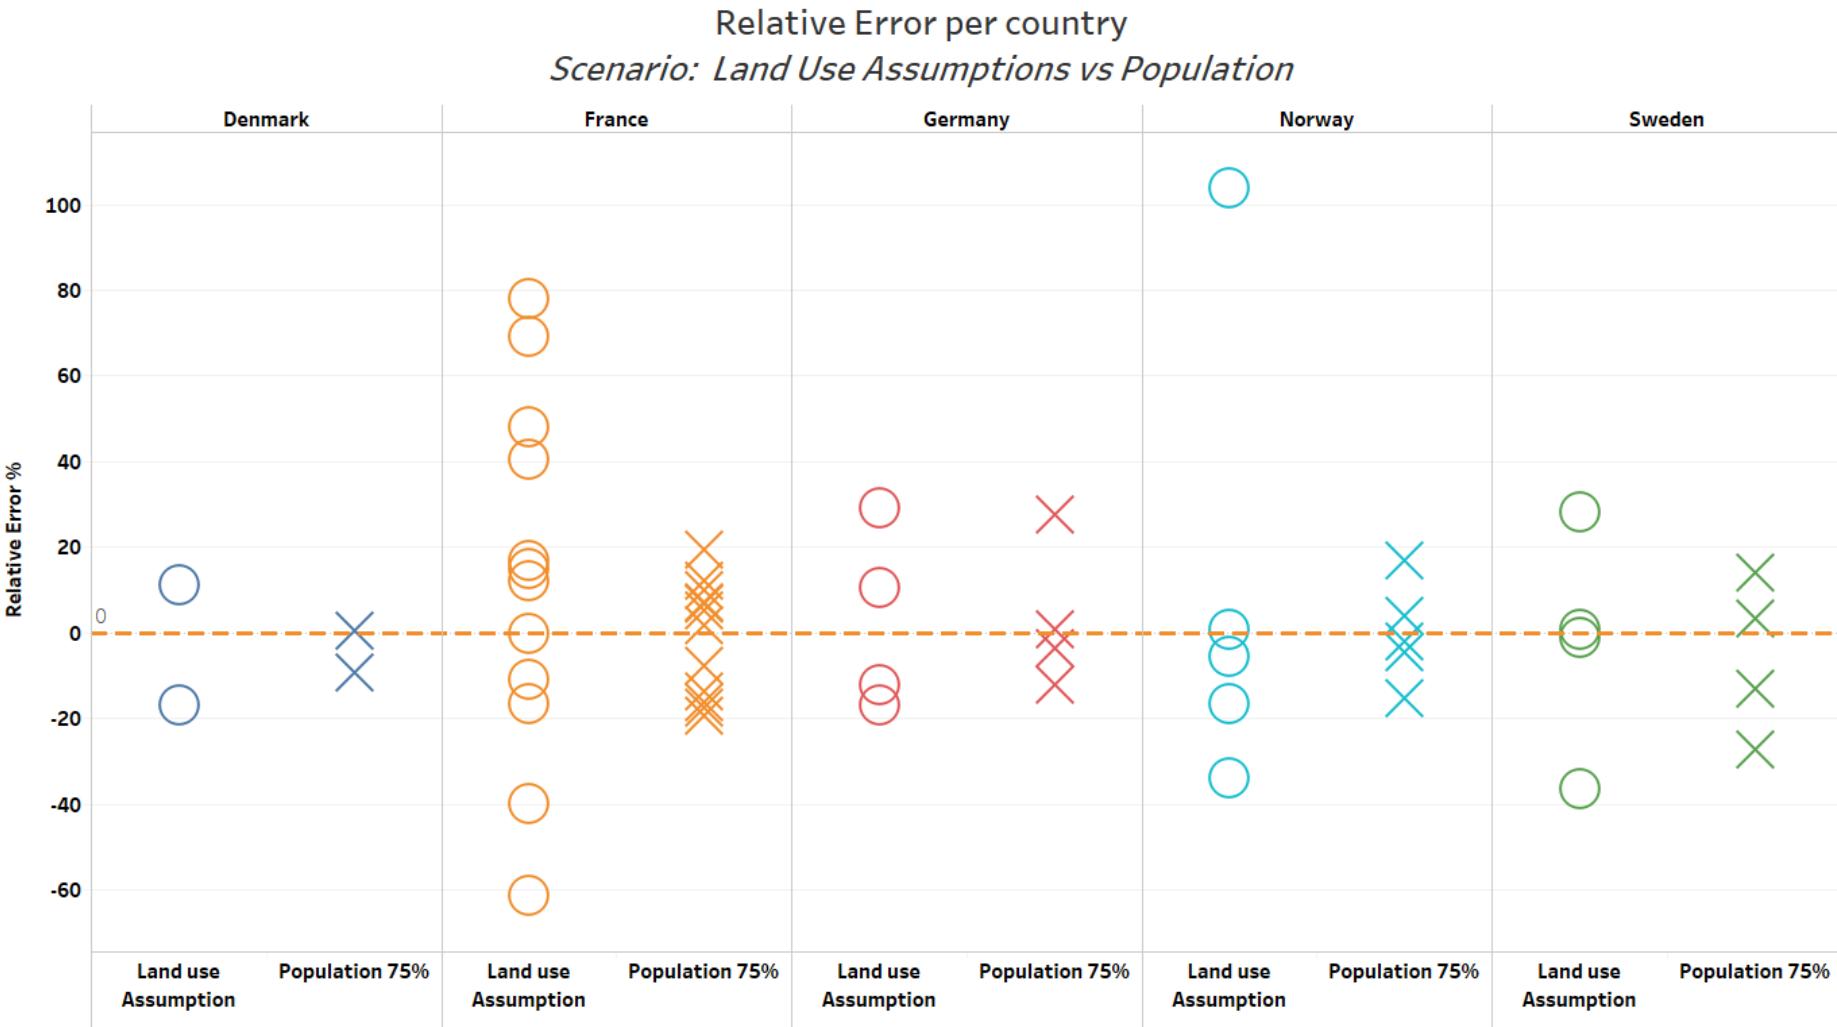

- 4 Transmission Systems Operator

France

- 12 Administrative areas

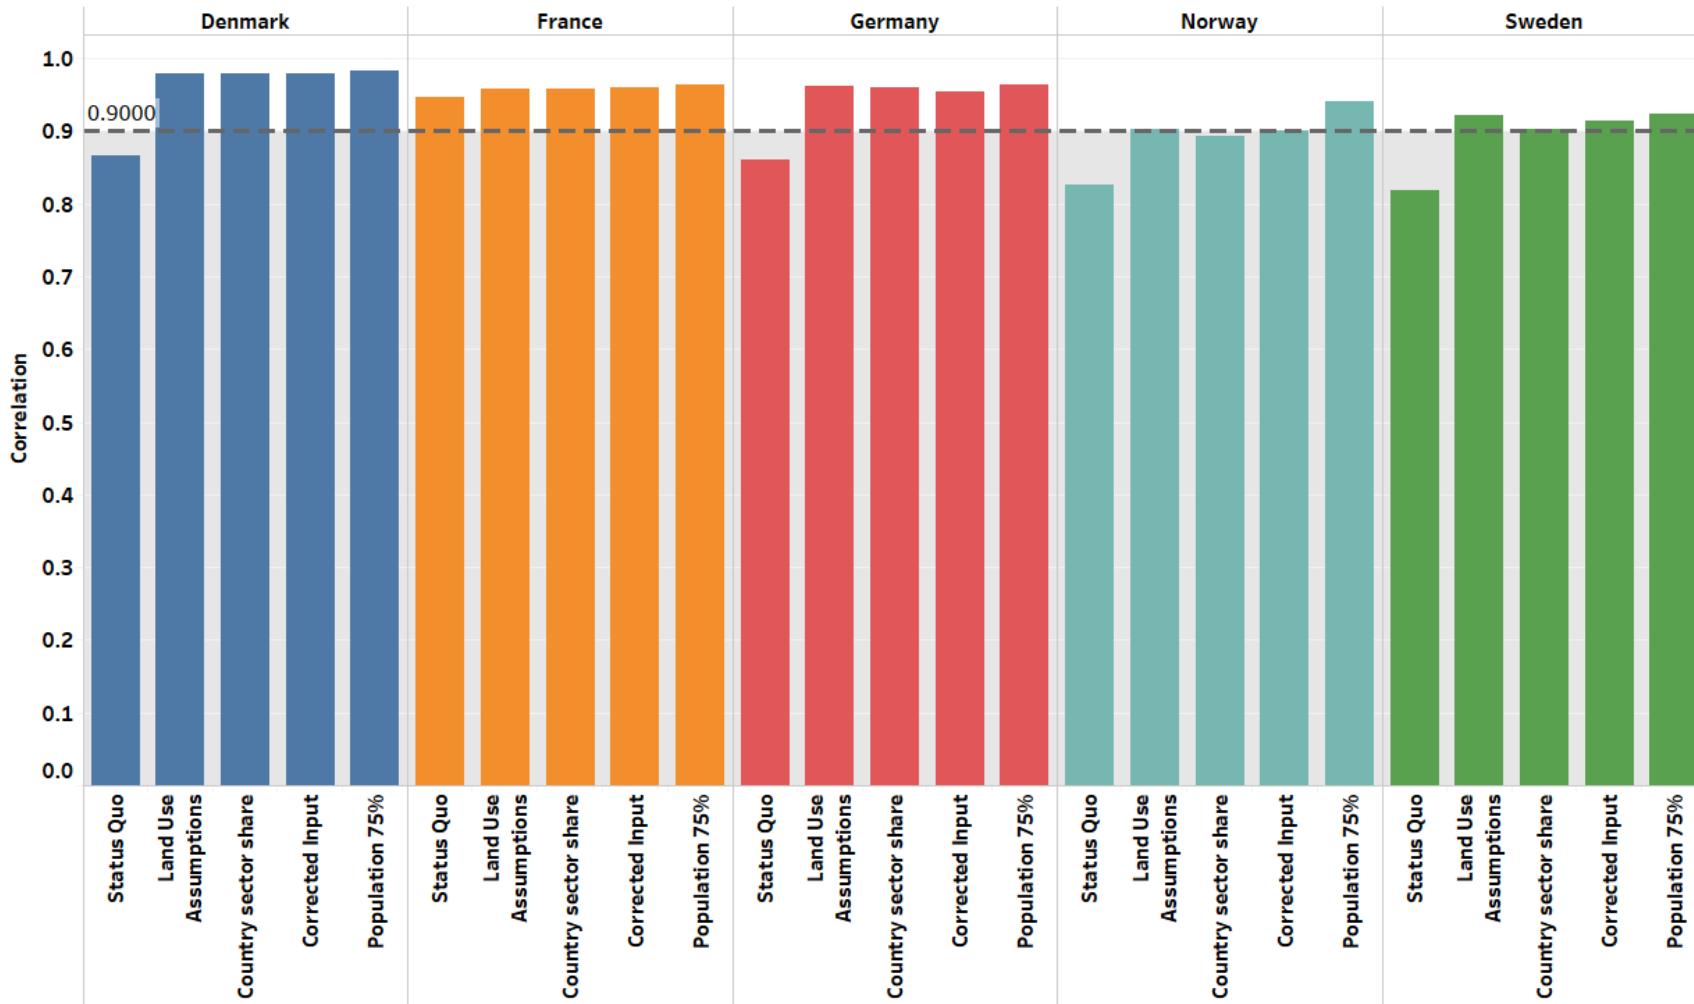

# Validation Yearly electricity demand

# Validation

## Load profile correlation

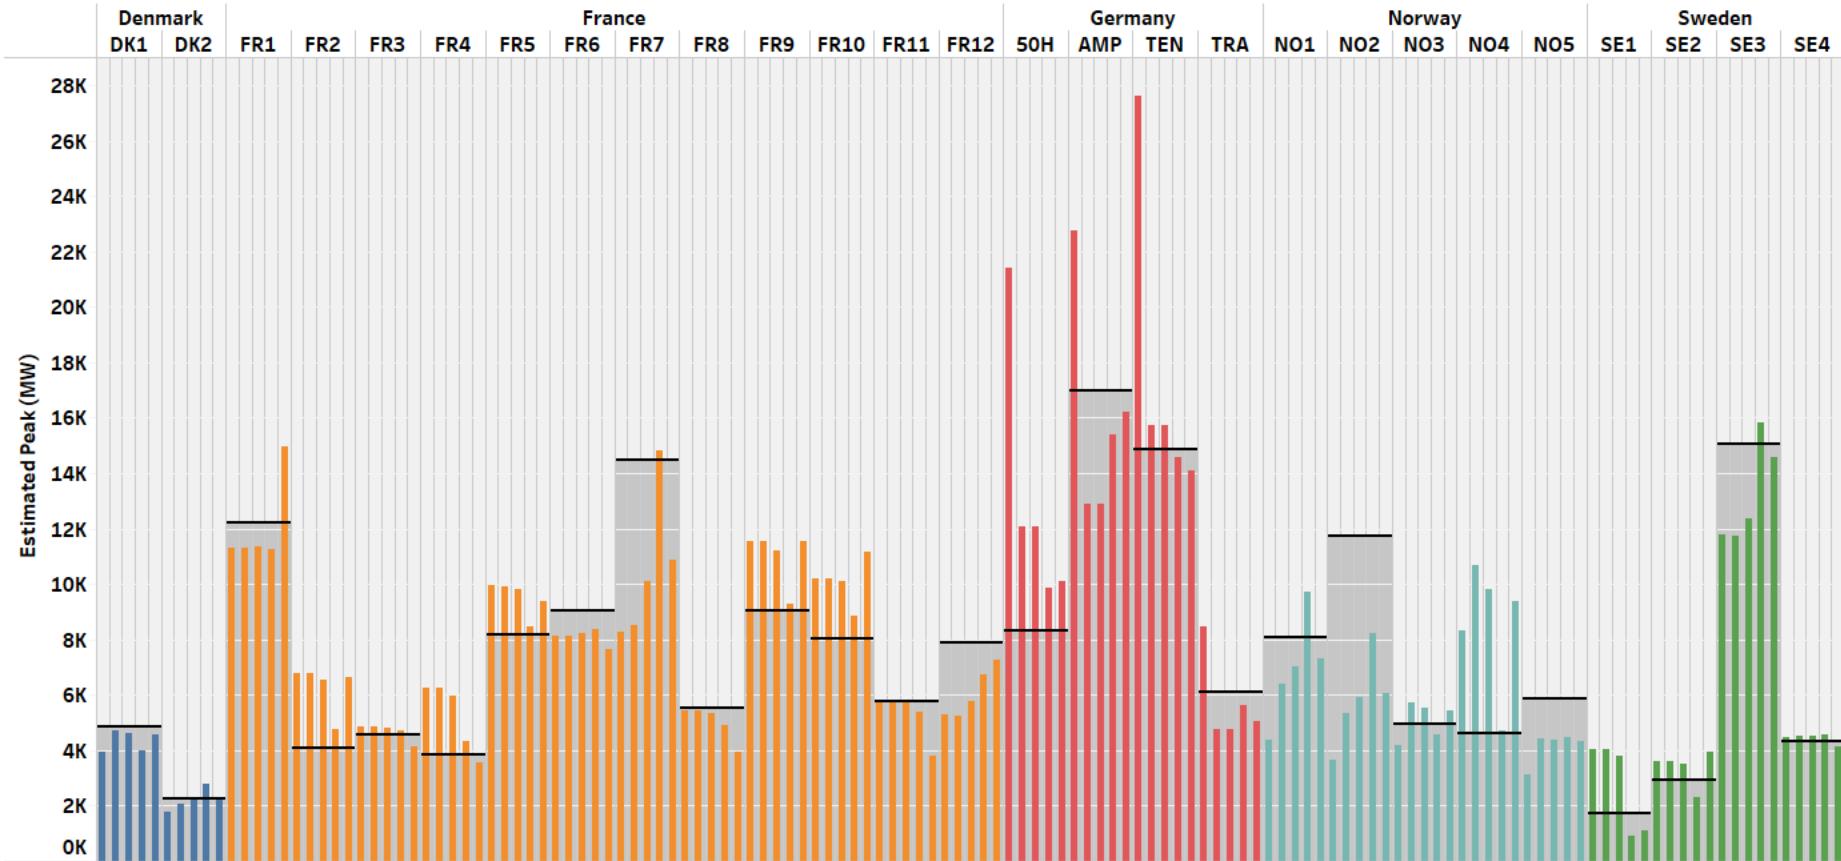

Correlation comparison

# Validation

## Peak load

### Peak Load Comparison

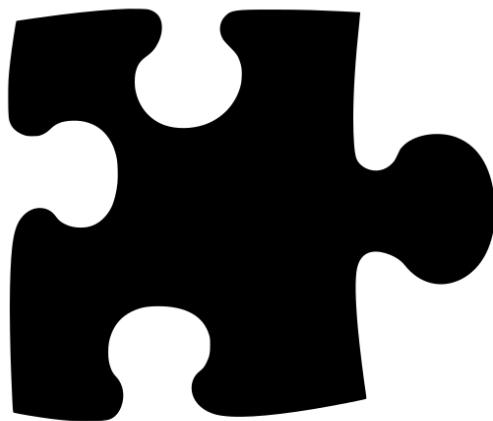

The order of the comparison scenarios are as follow for each region: Status Quo, Corrected Input, Country Sector Share, Land use Assumptions, Population 75%

The black line in each region represents the real peak value.

# Use cases

**GitHub:**  
[tum-ens/  
generate-models/  
generate\\_load\\_timeseries](https://github.com/tum-ens/generate-models/tree/main/generate_load_timeseries)

- Generation of load time series for any user-defined regions, particularly cities
- Generation of high resolution electricity demand map
- Application of sector-specific assumptions, so that the total load, its peak and its shape can be varied for the future

# Accepted publication at ESR

## Impact of the Choice of Regions on Energy System Models

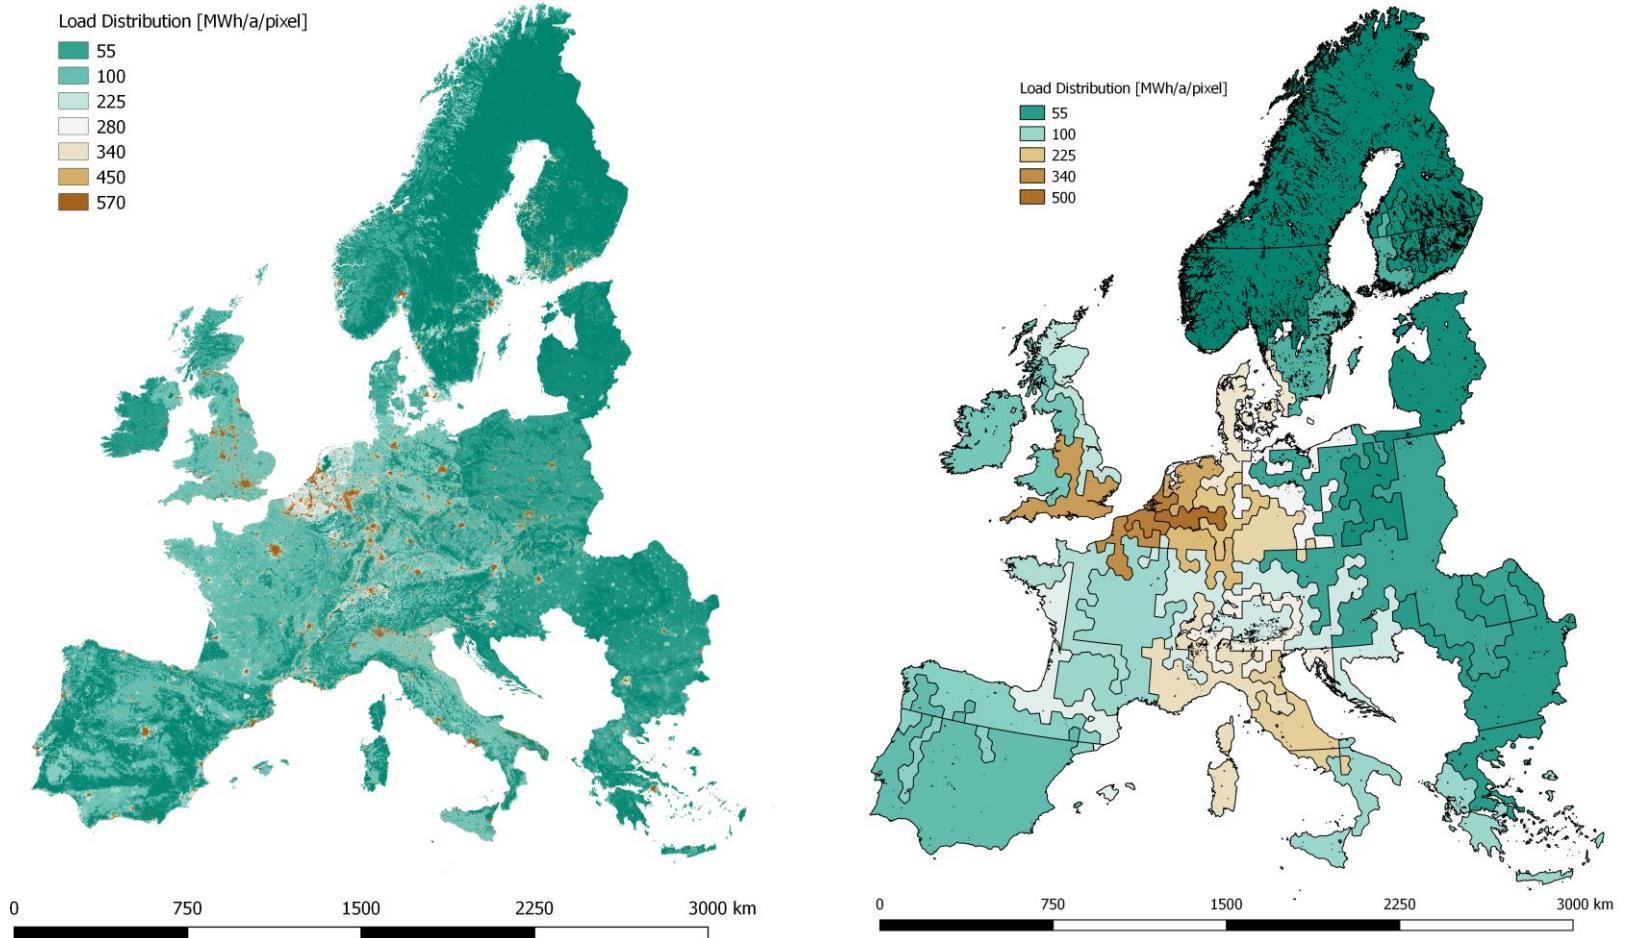

Kais Siala, Mohammad Youssef Mahfouz

*Technical University of Munich, Chair of Renewable and Sustainable Energy Systems*

### Highlights

- We develop a spatial clustering method for high resolution data.
- We cluster rasters of load density distribution and solar and wind potentials.
- We create energy system models with different shapes for the regions in Europe.
- Comparison with models based on countries show large discrepancies for the future.
- We use the method for a geographic sensitivity analysis to derive robust results.

# Accepted publication at ESR

# Summary and next steps

Empirical method allows the obtention of electricity time series for any region, provided that the input time series is provided for an overlapping geographic coverage.

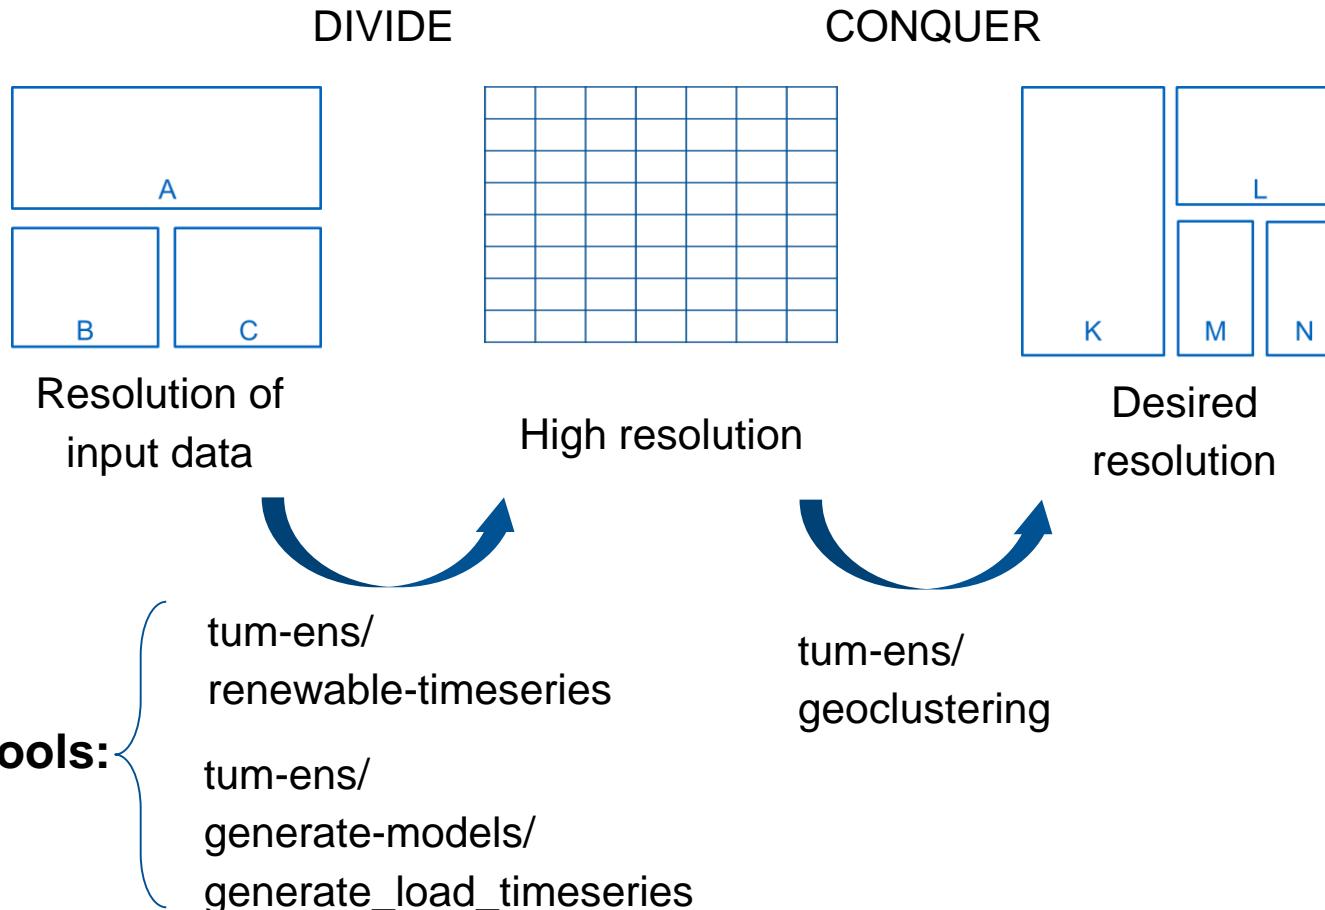

Diversity in terms of peak load, profiles and sub-regional total demand, which was not possible with econometric methods.

Correlation factors >90% and relative errors for total demand below 20%.

In the near future: comparison of performance with other disaggregation methods.

# Summary and next steps
