2. Univ.-Prof. A. Schnieke, Ph.D.

Die Dissertation wurde am07.05.2013..... bei der Technischen Universität München eingereicht und durch die Fakultät Wissenschaftszentrum Weihenstephan für Ernährung, Landnutzung und Umwelt am19.09.2013..... angenommen.

You cannot help dealing with the limited information you have as if it were all there is to know. You build the best possible story from the information available to you, and if it is a good story, you believe it. Paradoxically, it is easier to construct a coherent story when you know little, when there are fewer pieces to fit into the puzzle. ...

TNF-α	Tumor necrosis factor-alpha
Tris	2-Amino-2-hydroxymethyl-propane-1,3-diol
UV	Ultraviolet
VO₂	Oxygen consumption rate

SUMMARY

DJ-1 is a multifunctional, evolutionarily ancient protein which is ubiquitously expressed in humans and mice. The diverse functions of DJ-1 including the protection from oxidative stress and apoptosis as well as maintenance of mitochondrial integrity can be attributed to its ability to interact with RNA as well as with numerous proteins. Moreover, mutations in the *DJ-1* (*PARK7*) gene are associated with inherited forms of Parkinson's disease (PD) and oxidatively damaged DJ-1 plays a role in aging and neurodegenerative diseases including Alzheimer and sporadic PD. Mouse lines deficient in *Dj-1* (*Dj-1^{-/-}*), however, do not show the age-dependent degeneration of dopaminergic neurons typical for PD.

In the present study, DJ-1 emerged as a candidate from a proteome analysis investigating alterations in the hypothalamus in response to a short-term diet intervention. Three mouse strains differing in their susceptibility to diet-induced obesity (DIO) were fed a high-fat (HF) or control diet for 10 days. Among the differentially expressed proteins, DJ-1 was more abundant in the HF diet groups of all strains as compared to the respective control groups. The DJ-1 protein pool comprises different post-translational modified isoforms. Therefore, we separated hypothalamic protein extracts based on their isoelectric point with subsequent immunodetection of DJ-1. Quantification revealed an increase in acidic DJ-1 isoforms in the hypothalamus of HF diet-fed mice relative to the control group, validating the initial proteome result. A similar shift in the DJ-1 isoform pattern was detected in the brain, skeletal muscle, pancreas, and liver but not in epididymal white adipose tissue.

We furthermore investigated the gene-diet interaction in mice lacking *Dj-1*. The susceptibility of *Dj-1^{-/-}* mice to DIO is similar to wildtype mice with regard to body mass development but HF diet-feeding for 14 weeks resulted in higher fat accumulation in *Dj-1^{-/-}* mice at the expense of lean mass. This effect was transient: With a prolonged feeding duration and/or advanced age, the fat mass was similar to wildtype mice, while the muscle mass was reduced in *Dj-1^{-/-}* mice independent of diet. The altered body composition was not caused by measurable changes in energy intake or expenditure while locomotor activity was generally lower in *Dj-1^{-/-}* mice. Our data imply that *Dj-1* deficiency and HF feeding interact to influence glucose levels and hypothalamic STAT3 phosphorylation without affecting glucose tolerance or anorectic leptin action. In a transcriptome analysis of the ventral hypothalamus, however, we illustrate that HF diet-feeding has a greater impact on gene regulation in the absence of *Dj-1*.

Based on these results, we speculate that DJ-1 plays a role in the metabolic adaptation to a change in nutrient abundance or composition: HF diet-feeding modulates DJ-1 resulting in the maintenance of normal cellular homeostasis. When DJ-1 and its stabilizing function are absent, mice cope less efficient with metabolic changes induced by HF diet-feeding but are

finally able to compensate for the missing mechanisms. Our findings furthermore support a possible convergence or interaction of molecular pathways involved in obesity as well as neurodegeneration. Finally, obesity-associated metabolic changes might contribute to lower the threshold and therefore accelerate the development of age-related neurodegenerative diseases.

ZUSAMMENFASSUNG

DJ-1 ist ein multifunktionales, evolutionär frühzeitig entstandenes Protein, das sowohl im Menschen als auch in der Maus ubiquitär exprimiert wird. Unter anderem schützt DJ-1 vor oxidativem Stress und Apoptose und trägt zum Erhalt mitochondrialer Integrität bei. Die vielfältigen Funktionen von DJ-1 lassen sich auf die Fähigkeit, sowohl mit RNA als auch mit zahlreichen Proteinen interagieren zu können, zurückführen. Mutationen im *DJ-1 (PARK7)*-Gen wurden ferner mit erblichen Formen von Parkinson-Krankheit assoziiert und oxidativ geschädigtes DJ-1 spielt eine Rolle beim Altern und neurodegenerativen Erkrankungen wie der Alzheimer- und der sporadischen Parkinson-Erkrankung. *Dj-1* defiziente Mauslinien zeigen hingegen keine der für die Parkinson-Krankheit typischen altersabhängigen Degeneration dopaminerger Neurone.

In der vorliegenden Arbeit wurde DJ-1 als Kandidat einer Proteomstudie identifiziert, in der Veränderungen im Hypothalamus durch eine kurzzeitige Futterumstellung untersucht wurden. Hierbei erhielten drei Mausstämme mit unterschiedlicher Anfälligkeit gegenüber Diät-induzierter Adipositas für 10 Tage entweder fettreiches oder Kontrollfutter. Unter den differentiell exprimierten Proteinen war DJ-1 in den fettreich gefütterten Gruppen aller Stämme verstärkt im Vergleich zur jeweiligen Kontrollgruppe zu finden. Die Gesamtheit des DJ-1-Proteins setzt sich aus mehreren post-translational modifizierten Isoformen zusammen. Um die einzelnen Isoformen zu quantifizieren, trennten wir hypothalamische Proteinextrakte nach dem isoelektrischen Punkt auf und detektierten DJ-1 anschließend immunologisch. Die Quantifizierung zeigte ein Anstieg der saureren DJ-1 Isoformen im Hypothalamus von fettreich gefütterten Mäusen relativ zur Kontrollgruppe und bestätigte damit den initialen Proteombefund. Eine ähnliche Verschiebung des DJ-1 Isoformenmusters wurde im Gehirn, im Skelettmuskel, im Pankreas und der Leber, nicht aber im epididymalen weißen Fettgewebe detektiert.

Darüber hinaus untersuchten wir die Interaktion des Gens mit einer fettreichen Fütterung in *Dj-1* defizienten (*Dj-1*^{-/-}) Mäusen. Im Hinblick auf die Körpergewichtsentwicklung war die Anfälligkeit gegenüber diät-induzierter Adipositas in *Dj-1*^{-/-} Mäusen ähnlich der von wildtypischen Mäusen. Nach 14-wöchiger Fütterung mit fettreichem Futter

war jedoch eine höhere Fettakkumulation in *Dj-1*^{-/-} Mäusen auf Kosten der fettfreien Masse zu beobachten. Dieser Effekt war transient: Die Fettmasse glich sich mit längerer Fütterungsdauer und/oder fortgeschrittenem Alter der von Wildtyp-Mäusen an, während die Muskelmasse in *Dj-1*^{-/-} Mäusen unabhängig von der Futterart reduziert war. Die veränderte Körperzusammensetzung konnte nicht auf messbare Änderungen in der Energieaufnahme oder dem Energieverbrauch zurückgeführt werden, wohingegen die lokomotorische Aktivität der *Dj-1*^{-/-} Mäuse generell niedriger war. Unsere Daten deuten darauf hin, dass die *Dj-1*-Defizienz in Wechselwirkung mit der fettreichen Fütterung sowohl die Plasmaglucoosespiegel als auch die hypothalamische STAT3-Phosphorylierung beeinflusst, was jedoch keine Auswirkungen auf die Glucosetoleranz oder die anorektische Leptinantwort hat. In einer Transkriptomanalyse des ventralen Teils des Hypothalamus zeigen wir jedoch, dass die Fütterung mit fettreichem Futter einen größeren Einfluss auf die Genregulation in der Abwesenheit von *Dj-1* hat.

Ausgehend von diesen Ergebnissen spekulieren wir, dass DJ-1 eine Rolle bei der metabolischen Anpassung an eine veränderte Quantität oder Qualität der zugeführten Nährstoffe spielt: Durch die fettreiche Fütterung werden DJ-1-Modifikationen induziert und modifiziertes DJ-1 trägt so zur Aufrechterhaltung der normalen zellulären Homöostase bei. Fehlt DJ-1 und damit seine stabilisierende Funktion, können Mäuse weniger effizient mit den metabolischen Änderungen, die durch eine fettreiche Fütterung induziert werden, umgehen. Letztendlich sind sie aber in der Lage, die abwesenden Mechanismen zu kompensieren. Unsere Befunde unterstützen weiterhin eine mögliche Überschneidung oder Interaktion von molekularen Signalwegen, die sowohl bei Adipositas als auch bei Neurodegeneration eine Rolle spielen.

Adipositas-bezogene metabolische Veränderungen könnten dazu beitragen, die Schwelle der Entwicklung von altersabhängigen neurodegenerativen Erkrankungen herabzusetzen und deren Entstehung somit beschleunigen.

1 INTRODUCTION

1.1 Common obesity - A polygenic trait

Obesity and overweight have emerged to a worldwide public health challenge. Having more than doubled since 1980, global obesity has ceased from being considered a problem of merely high-income countries [WHO 2012]. According to the World Health Organization, a person with a body mass index (BMI = body weight [kg]/height [m]²) higher than 25 is considered overweight, while a BMI exceeding 30 indicates obesity [WHO 2012]. In Germany the prevalence of obesity has continued to rise in the last two decades affecting about one quarter of men as well as woman according to the latest projection [Mensink et al. 2012].

Obesity results from a chronic energy surplus of the organism majorly as a consequence of adverse lifestyle and environmental factors, including the unrestricted access to high caloric, energy dense foods and low physical activity. Notably, already a divergence of 1 % in calories consumed versus energy expended maintained over a few years is sufficient for extensive weight gain [Brown 2008]. With the exception of rare monogenic forms, the susceptibility to common forms of obesity is furthermore influenced by a large number of gene variants: 32 loci have been linked to obesity in genome-wide association studies [Speliotes et al. 2010]. However, based on an estimated BMI heritability of 0.4 to 0.7, the total identified variants explain only 2-4 % of the genetic variance [Hebebrand et al. 2010] indicating that each variant has only subtle effects.

Since overweight and obesity are associated with comorbidities like cardiovascular diseases, type 2 diabetes mellitus and several forms of cancer [Daniels 2009; WHO 2012], a lot of work has been done trying to identify the factors that influence energy homeostasis in order to develop new drugs to treat obesity. Multiple central and peripheral components have been determined, resulting in a complex network of energy balance regulation. In this network, the hypothalamus is the brain area where many peripheral signals are first integrated. In fact, in all known monogenic forms of obesity, hypothalamic pathways are impaired affecting satiety and food intake [Lee et al. 2010]. One aim of the present thesis was to identify hypothalamic alterations associated with the development of diet-induced obesity (DIO) in mice.

1.2 Hypothalamus – Function and dysfunction in energy balance regulation

1.2.1 Physiological regulation of energy homeostasis

The hypothalamus plays a central role in controlling energy homeostasis, which aims to promote stable body fat stores regarded over a longer period of time, by regulating food intake and energy expenditure [Morton et al. 2006]. It integrates various hormonal and neuronal signals that inform about short-term changes in nutrient availability (e.g. satiety signals from the gastrointestinal tract) and long-term energy status (e.g. adipose tissue derived adipokines) (Fig. 1-1) [Gale et al. 2004; Zeltser et al. 2012]. Circulating factors need to overcome the blood-brain barrier via diffusion or saturable transport mechanisms in order to reach their central target sites. Within the ventral hypothalamus, the arcuate nucleus (ARC) is responsive to a wide variety of hormones and nutrients due to special properties of the blood-brain barrier in this region [Schwartz et al. 2000; Cone et al. 2001; Varela & Horvath 2012]. Additionally, some axonal processes of ARC neurons reach into the portal vein potentially having direct access to circulating factors and thereby circumventing the blood-brain barrier [Cone et al. 2001; Münzberg 2008].

The ARC contains two distinct first-order neuron populations exerting opposing actions on energy balance regulation: Neurons coexpressing neuropeptide Y (NPY) and agouti-related protein (AgRP) have an orexigenic effect promoting food intake, while neurons coexpressing pro-opiomelanocortin (POMC) and cocaine and amphetamine related transcript (CART) exert anorexigenic action (Fig. 1-1) [Bell et al. 2005]. For instance, both neuron populations express receptors for leptin, a hormone secreted in proportion to the body fat stores [Maffei et al. 1995]. While the binding of leptin inhibits NPY/AgRP neurons, it stimulates POMC/CART neurons [Schwartz et al. 2000]. Additionally, NPY/AgRP neurons inhibit POMC/CART neurons via the release of the neurotransmitter γ -aminobutyric acid (GABA) [Bell et al. 2005]. In addition, a wide range of further nutrient and hormonal signals including insulin, ghrelin, glucose, amino acids and free fatty acids are sensed by POMC/CART and NPY/AgRP neurons (Fig.1-1). Consequently, the balance of the activity between the two neuron sets is a major regulator of feeding behavior and body weight [Zeltser et al. 2012]. Orexigenic and anorexigenic signals are relayed to second order neurons in other hypothalamic nuclei (Fig. 1-1). POMC is cleaved post-translationally into several products one of which is α -melanocyte stimulating hormone (α -MSH) that activates the melanocortin 4 receptor (MC4R) in other hypothalamic areas thereby inhibiting appetite [Gale et al. 2004]. AgRP, on the other hand, acts through the inhibition of the MC4R and, together with the action of NPY, promotes food intake [Fan et al. 1997; Broberger et al. 1998]. Moreover, the hypothalamus interacts with satiety circuits located in the brainstem [Schwartz et al. 2000]. The hypothalamic integration of these signals together with reward and motivation-related signals

from the midbrain-dopamine system and cognitive information from the forebrain in a concerted manner result in the overall balance of food intake and energy expenditure (Fig. 1-1) [Blouet & Schwartz 2010]. Efferent output is realized by the autonomic or motoric nervous system or by hormone signaling via the hypothalamic-pituitary-adrenal axis. However, neural circuits of higher brain regions have the potential to override the homeostatic mechanisms, resulting in obesity or anorexia as extreme cases [Palmiter 2007].

Fig. 1-1. Homeostatic control of food intake. Circulating factors from the periphery are sensed by first order neurons within the arcuate nucleus (ARC): POMC/CART neurons exert anorexigenic action (-) while the activation of NPY/AgRP neurons leads to orexigenic effects (+) and the inhibition of POMC/CART neurons via the neurotransmitter γ -aminobutyric acid (GABA). Orexigenic and anorexigenic signals are relayed to second order neurons within the hypothalamus. The hypothalamus cross-talks with the brainstem that receives afferent input from the liver or GI tract transmitted through the vagus nerve and sympathetic fibres. Homeostatic circuits are modulated by dopaminergic pathways of the reward system and signaling from higher brain regions. Dark grey arrows indicate projections between brain areas. VTA - ventral tegmental area. NTS - nucleus of the solitary tract. GLP-1 - glucagon-like peptide 1. PYY₃₋₃₆ - peptide YY residues 3-36. CCK - cholecystikinin. MC4 - melanocortin 4. 3V - third ventricle. GI tract - gastrointestinal tract. Modified from Schwartz *et al.* [2000]; Varela & Horvath [2012]; Yeo & Heisler [2012].

1.2.2 Alterations in the hypothalamus associated with high fat intake and obesity

To develop overweight, the homeostatic system of energy balance regulation needs to be disturbed. Established obesity, however, involves an active defence of the elevated level of adiposity, hence the homeostatic pathways likely act on a shifted 'set-point' of body fat [Wisse *et al.* 2007; Leibel 2008]. The current state of knowledge regarding changes in the hypothalamus associated with high fat intake, which were also subject of this thesis, are summarized in the following focusing on findings from DIO rodent models.

Leptin and insulin resistance

One aspect of the pathophysiology of obesity is the loss of sensitivity towards leptin and insulin, both known to be negative feedback signals for adiposity [Bagdade *et al.* 1967; Considine *et al.* 1996; Schwartz *et al.* 1996; Münzberg *et al.* 2004; De Souza *et al.* 2005]. Since intracellular pathways exist that can be activated both by insulin and leptin, the impairment of one such mechanism may cause resistance to both hormones. Leptin and insulin signaling namely converge at the phosphatidylinositol-3-kinase (PI3K) pathway resulting in the activation of protein kinase B (PKB, also known as AKT) [Niswender & Schwartz 2003; Niswender *et al.* 2004; Varela & Horvath 2012] (Fig. 1-2). Activated PKB phosphorylates numerous substrates including the transcription factor Forkhead box protein O1 (FOXO1). FOXO1 is inhibited by phosphorylation and exported from the nucleus giving way to the binding of signal transducer and activator of transcription 3 (STAT3) to the *Pomc* and *Agrp* promoter, respectively, thereby stimulating *Pomc* and inhibiting *Agrp* expression [Morrison *et al.* 2005; Kim *et al.* 2006; Kitamura *et al.* 2006]. PKB further regulates the mammalian target of rapamycin (mTOR) [Cota *et al.* 2006], which responds to changes in nutrient availability. Moreover, a PI3K-dependent activation of the ATP-sensitive potassium channel (KATP) in response to insulin and leptin has been shown in hypothalamic neurons leading to a reduced firing rate [Spanswick *et al.* 1997; Niswender & Schwartz 2003]. The activation of KATP channels by physiological insulin levels is blunted in obese compared to lean leptin receptor-deficient rats [Spanswick *et al.* 2000].

As a mechanism underlying the hypothalamic resistance to leptin, an impaired negative feedback inhibition of the leptin receptor in the presence of chronically elevated leptin levels has been suggested [Maffei *et al.* 1995; Considine *et al.* 1996; Velloso & Schwartz 2011]. Binding of leptin to its receptor consequently leads to the induction of suppressor of cytokine signaling 3 (SOCS3) expression, an inhibitor of proximal leptin and insulin signalling (Fig.1-2) [Bjorbaek *et al.* 1999; Emanuelli *et al.* 2000; Rui *et al.* 2002; Mori *et al.* 2004].

In DIO, SOCS3 levels are increased in hypothalamic neurons likely leading to a blunted response to neuronal leptin and insulin action [Howard *et al.* 2004; Howard & Flier 2006; Ernst *et*

al. 2009; Velloso & Schwartz 2011]. Another inhibitor of leptin and insulin signal transduction is the protein-tyrosine phosphatase 1B (PTP1B, Fig. 1-2) [*Zabolotny et al. 2002; Picardi et al. 2008; Picardi et al. 2010*]. Similar to SOCS3, PTP1B expression is increased in the hypothalamus of obese rodents [*Cheng et al. 2002; White et al. 2009*]. Neuronal PTP1B knockout mice and rats deficient of PTP1B in hypothalamic areas are resistant to DIO and show enhanced sensitivity to hypothalamic leptin and insulin [*Bence et al. 2006; Picardi et al. 2008*].

Fig. 1-2. Insulin and leptin receptor-dependent activation of the PI3K pathway. The phosphatidylinositol-3-kinase (PI3K) is activated by phosphorylated insulin receptor substrate 1 or 2 (IRS1/2). IRS1/2 phosphorylation is mediated directly by the insulin receptor or indirectly by the leptin receptor through the janus kinase 2 (JAK2), upon binding of their respective substrate. Activated PI3K phosphorylates the second messenger phosphatidylinositol (4,5) bisphosphate (PIP₂) converting it into phosphatidylinositol (3,4,5) triphosphate (PIP₃). PIP₃ recruits and activates the phosphatidylinositol-dependent kinase 1 (PDK1), which in turn phosphorylates and thereby activates the protein kinase B (PKB, also known as AKT). Active PKB regulates the mammalian target of rapamycin (mTOR) pathway and activates ion channels. PKB further phosphorylates and thereby inhibits the transcription factor Forkhead box protein O1 (FOXO1). Leptin receptor induced activation of JAK2 further results in the phosphorylation of the signal transducer and activator of transcription 3 (STAT3) which forms dimers that act as a transcription factor. FOXO1 and STAT3 reciprocally regulate gene expression e.g. of the neuropeptides *Agrp* and *Pomc* or of the suppressor of cytokine signaling 3 (*Socs3*). SOCS3 and the protein-tyrosine phosphatase 1B (PTP1B) inhibit insulin and leptin receptor signaling via IRS1/2 or JAK2, respectively. Modified from *Morton et al. [2006]; Velloso & Schwartz [2011]*.

Inflammatory processes

Leptin and insulin resistance may result from processes linked to inflammation which are well documented to occur within the hypothalamus as a consequence of HF diet-consumption and obesity [De Souza et al. 2005; Posey et al. 2009; Wisse & Schwartz 2009; Thaler et al. 2010; Thaler et al. 2012]. The increased expression of the inflammatory cytokines TNF- α , IL-1 β and IL-6 in the hypothalamus of rats after several weeks of HF diet has been reported repeatedly [De Souza et al. 2005; Milanski et al. 2009; Moraes et al. 2009; Thaler et al. 2012] and central TNF- α administration is able to affect leptin and insulin signaling [Romanatto et al. 2007].

Inflammation-responsive signaling components activated by HF intake include (I) the serine/threonine kinase c-Jun-N-terminal kinase (JNK) that is involved in various processes such as neuronal proliferation and apoptosis [De Souza et al. 2005], (II) the inhibitor of nuclear factor kappa-B kinase (IKK), a serine kinase which activates the transcription factor nuclear factor- κ B (NF- κ B) [Zhang et al. 2008] and (III) the protein kinase C-theta (PKC-theta), a serine/threonine kinase that mediates T-cell receptor signaling [Benoit et al. 2009]. Analogue to SOCS3 and PTP1B, the kinases IKK, JNK and PKC-theta are able to inhibit leptin and insulin signaling via inhibition of STAT3 as well as the insulin receptor substrate 1 and 2 (IRS1/2), proteins that are phosphorylated upon activation of the leptin or insulin receptor, respectively [Velloso & Schwartz 2011]. Moreover, SOCS3 and PTP1B can also be induced by inflammatory processes [Zabolotny et al. 2002; Velloso & Schwartz 2011].

Several mechanisms have been suggested to trigger hypothalamic inflammation. Saturated fatty acids, a main component of HF diets, increase the expression and activity of the toll-like receptor 4 (TLR4) [Milanski et al. 2009] which leads to IKK β activation and NF- κ B-dependent expression of inflammatory cytokines [Akira 2003; Kleinridders et al. 2009]. TLR4 signaling as well as the direct action of saturated fatty acids can induce endoplasmic reticulum (ER) stress [Zhang et al. 2008; Milanski et al. 2009]. Increased ER stress has been shown to inhibit leptin signaling in the hypothalamus of obese mice and activate the unfolded protein response [Ozcan et al. 2009], a pathway aiming to restore ER homeostasis [Schroder & Kaufman 2005]. Under prolonged stress, however, an overloaded unfolded protein response is capable of initiating apoptosis [Schroder & Kaufman 2005]. The induction of apoptosis by dietary fats has indeed been shown to occur in hypothalamic neurons of rats [Moraes et al. 2009].

Autophagy

Hypothalamus-linked autophagy¹, a cellular recycling process for cytoplasmic material and excess or defective organelles [Shintani & Klionsky 2004], has recently been shown to be involved in the pathogenesis of obesity [Coupe & Bouret 2012]. As an alternative energy source during starvation, autophagy is negatively regulated by the mTOR pathway [Pattingre et al. 2008; Kaushik et al. 2011] and dysfunction of autophagy may result in abnormal mitochondrial function and oxidative or nitrative stress [Lee et al. 2012]. Mice in which autophagy was selectively deactivated in AgRP neurons reduce food intake and adiposity [Kaushik et al. 2011]. In contrast, in POMC neurons, this defect resulted in higher body weights with increased adiposity and leptin resistance along with hyperphagia and impaired glucose tolerance [Coupe & Bouret 2012; Kaushik et al. 2012; Quan et al. 2012]. Mechanistically, loss of autophagy from POMC neurons decreases α -MSH levels [Kaushik et al. 2011] and reduces the density of POMC-containing projections [Coupe & Bouret 2012] suggesting a role of autophagy in promoting structural changes [Varela & Horvath 2012].

Synaptic plasticity

The term 'synaptic plasticity' implies changes in the magnitude of a synaptic reaction regulated at different levels including synapse strength, synapse number and intrinsic neuronal excitability [Zeltser et al. 2012]. Hypothalamic neurons have the potential to undergo continuous rewiring, a process that is influenced by a variety of factors including leptin and nutrients [Pinto et al. 2004; Horvath 2006]. HF feeding leads to hypothalamic alterations in synaptic plasticity: A high dietary fat intake reduces the amount of nerve terminals in the ARC and lateral hypothalamus of rats [Moraes et al. 2009] and the amount of synapses on POMC neurons is altered in DIO rats and mice compared to control diet-fed animals [Horvath et al. 2010; Ravussin et al. 2011].

Taken together, there is convincing evidence that HF feeding affects the hypothalamus at several levels (Fig. 1-3). However, many open questions remain to be answered. One aspect is the contribution of microglia and their interaction with neurons and other glial cells to HF diet-induced inflammation, as the TLR4 is predominantly expressed by microglia in the central nervous system [Lehnhardt et al. 2003]. In addition, microglia play a role in synaptic remodeling [Cullheim & Thams 2007; Ransohoff & Perry 2009]. Another issue is the influence of the diet composition on different outcomes associated with HF feeding in the hypothalamus. As shown in pair-feeding experiments, HF diet-induced apoptosis is not caused by increased energy intake and weight gain *per se* [Moraes et al. 2009]. Finally, the cause-consequence

¹The term 'autophagy' used in this thesis refers to macroautophagy.

relationship of alterations in the central nervous system associated with a HF diet is not well elucidated. It was demonstrated that hypothalamic inflammation and reactive gliosis were present before extensive weight gain, subsided in the following but returned permanently with continued HF feeding [Thaler et al. 2012]. Alterations occurring early during HF feeding are more likely to be causal for the development of obesity and should thus be separated from chronic manifestations of the disease.

Fig. 1-3. Cellular mechanisms shown to occur in the hypothalamus upon excess nutrient intake. Arrows indicate putative causal connections. Whether the suggested mechanisms are causal for or consequences of obesity remains to be clarified. ER – Endoplasmic reticulum. ROS – Reactive oxygen species. UPR – Unfolded protein response.

1.3 Obesity and neurodegeneration

It has long been suggested that obesity may accelerate brain aging [Bruce-Keller et al. 2009] and cognitive decline in humans [Sorensen et al. 1983; Jeong et al. 2005; Gunstad et al. 2007; Singh-Manoux et al. 2012]. Experimental studies with rodent models investigating the putative influence of dietary energy intake on brain function show decreased spatial learning abilities in rats after several months of a diet rich in fat and sucrose [Molteni et al. 2002; Stranahan et al. 2008] as well as in leptin receptor-deficient mice and rats [Li et al. 2002] indicating a cognitive impairment. Cognitive performance was also reduced in old DIO mice [Farr et al. 2008; Morrison et al. 2010]. As a mechanism, elevated plasma triglyceride levels were suggested because the cognitive function was improved after triglyceride levels were lowered pharmacologically [Farr et al. 2008].

Recently, obesity and metabolic dysfunction have also been recognized as a possible risk factor for neurodegenerative disorders such as Alzheimer's disease, depression or Parkinson's disease (PD) [Doherty 2011; Lee 2011; Farooqui et al. 2012]. Moreover, the susceptibility to chemically induced neurodegeneration was increased in mice and rats fed a HF diet [Choi et al. 2005; Morris et al. 2010] as well as in the genetically obese *ob/ob* mouse model [Sriram et al. 2002].

PD is a neurodegenerative disorder subsuming the movement-related symptoms bradykinesia, rigidity, resting tremor and postural instability that result from a loss of dopaminergic neurons in the substantia nigra, a part of the ventral midbrain [Thomas & Beal 2011]. Although majorly a sporadic disorder, several genetic loci termed PARK1 to PARK16 have been linked to inherited forms of PD [Thomas & Beal 2011]. Increased measures of adiposity have been associated with an elevated risk for the development of PD in a Finish study population [Hu et al. 2006], among Japanese-American men [Abbott et al. 2002] as well as in the Health Professional Follow-up study (HPFS) and the Nurses' Health Study (NHS) cohorts [Chen et al. 2004]. However, in the Cancer Prevention Study II Nutrition cohort no relationship between BMI, weight change or waist circumference and the risk of PD was found [Palacios et al. 2011].

As an underlying mechanism linking metabolic disorders and neurodegeneration, an impairment of insulin and leptin signaling, respectively, has been suggested [Doherty 2011; Kaidanovich-Beilin et al. 2012]. Thus, the threshold for developing age-related neurodegenerative diseases may be lowered by obesity-associated metabolic changes.

1.4 DJ-1 (PARK7) – a multifunctional redox-regulated protein

In this thesis, we identified DJ-1 (PARK7) as a protein responsive to HF diet-feeding in mice. DJ-1 was first described in 1997 as an oncogene able to transform mouse embryonic fibroblast cells [Nagakubo *et al.* 1997]. Six years later, DJ-1 was linked to neurodegeneration when mutations in the *DJ-1* gene were associated with autosomal recessive early-onset parkinsonism [Bonifati *et al.* 2003a]. Later, oxidative damage of DJ-1 was shown in sporadic Parkinson's and Alzheimer's disease as well as in other neurodegenerative diseases and aging [Choi *et al.* 2006; Zhong & Xu 2008; Natale *et al.* 2010]. For this reason, the molecular impact of DJ-1 regarding oxidative stress-related neurodegeneration has been widely studied.

DJ-1 is an evolutionary ancient protein with homologs present in diverse organisms [Bandyopadhyay & Cookson 2004; Kahle *et al.* 2009]. In humans and mice, DJ-1 is ubiquitously expressed [Nagakubo *et al.* 1997; Taira *et al.* 2001; Bonifati *et al.* 2003b; Niki *et al.* 2003; Zhang *et al.* 2005a]. Within the brain, DJ-1 is present in neurons of different neurotransmitter type and in all glial cell types [Bader *et al.* 2005]. DJ-1 is further found in red blood cells and plasma and is secreted from various cancer cells, constituting a potential cancer biomarker [Le Naour *et al.* 2001; MacKeigan *et al.* 2003; Hod 2004; Pardo *et al.* 2006; Shi *et al.* 2010; Xu *et al.* 2010; Lin *et al.* 2012].

Both the human and mouse DJ-1 protein consist of 189 amino acids, respectively, and show 91.5 % identity (Fig. 1-4 A). Human DJ-1 contains three cysteines (Cys) at position 46, 53 and 106 as well as five methionines that are all highly conserved [Bandyopadhyay & Cookson 2004; Waak *et al.* 2009]. Murine DJ-1 contains an additional cysteine at position 87 as well as three additional methionines (Fig. 1-4 A).

Fig. 1-4. Primary and quaternary structure of the DJ-1 protein. (A) Alignment of human and mouse DJ-1 amino acid sequence. Identical amino acids are highlighted dark grey. Cysteines are shown in yellow, methionines in blue. (B) Ribbon diagram of human dimeric DJ-1 (from Wilson [2011]). Monomers are shown in gold and blue, respectively. Cysteines are shown in yellow. C – carboxy terminus. N – amino terminus.

Crystal structures have shown that DJ-1 exists as a homodimer and dimerization is crucial for its stability and function [Honbou et al. 2003; Huai et al. 2003; Miller et al. 2003; Tao & Tong 2003; Wilson et al. 2003; van der Brug et al. 2008]. Cys-45 and Cys-53 are located close to the dimer interface, while Cys-106 is located at the bottom of a narrow cleft (Fig. 1-4 B) [Wilson et al. 2003; Canet-Aviles et al. 2004]. Cysteine and methionine residues are prone to post-translational oxidation yielding several possible isoforms² that can be separated according to their isoelectric points (pI). Multiple DJ-1 isoforms have been described with a pI ranging from 5.4 to 6.7 and low pI forms are increased in cultured cells exposed to oxidative stresses as well as in human brain under neurodegenerative conditions (Fig. 1-5 A) [Mitsumoto & Nakagawa 2001; Bandopadhyay et al. 2004; Canet-Aviles et al. 2004; Kinumi et al. 2004; Taira et al. 2004; Zhou & Freed 2005; Choi et al. 2006; Kim et al. 2009b; Natale et al. 2010]. Among the DJ-1 cysteine residues, Cys-106 is the most sensitive to oxidative modification because it is accessible by small molecules like peroxides, and oxidized Cys-106 has been identified in low pI forms of DJ-1 [Wilson et al. 2003; Canet-Aviles et al. 2004; Kinumi et al. 2004; Zhou et al. 2006; Inden et al. 2011]. Thus, Cys-106 is expected to be crucial for DJ-1 function, although there is no consent about to which extent its oxidation occurs *in vivo* [Blackinton et al. 2009; Wilson 2011]. In addition to the post-translational modifications of cysteines, methionine residues can also be oxidized [Choi et al. 2006] and DJ-1 can undergo SUMOylation [Shinbo et al. 2006]. Thus, it is sensible to recognize DJ-1 total protein as a pool of isoforms with different modifications and the relative amounts of these isoforms are likely of importance with respect to its overall activity [Natale et al. 2010].

The subcellular distribution of the DJ-1 pool is dynamic [Kahle et al. 2009]. Predominantly, DJ-1 is a cytosolic protein with some nuclear and mitochondrial localization [Taira et al. 2004; Zhang et al. 2005a]. However, in response to oxidative stress, some of the cytosolic DJ-1 pool translocates to the nucleus and mitochondria (Fig. 1-5 B) [Nagakubo et al. 1997; Canet-Aviles et al. 2004; Blackinton et al. 2005; Lev et al. 2008; Blackinton et al. 2009; Zhong et al. 2009].

DJ-1 plays a role in diverse biological processes (Fig. 1-5 C). As indicated above, DJ-1 is involved in the cellular oxidative stress response. It prevents cell death triggered by a variety of oxidative stresses in various *in vitro* models as well as in rodents [Yokota et al. 2003; Kim et al. 2005b; Zhou & Freed 2005; Shinbo et al. 2006]. Down-regulation of DJ-1 on the other hand, renders cells more susceptible to such stimuli [Yokota et al. 2003; Martinat et al. 2004; Taira et al. 2004; Junn et al. 2005; Zhou & Freed 2005]. The DJ-1 dependent protection from oxidative stress has been linked to the up-regulating of cellular glutathione levels in a rat dopaminergic cell line and primary rat midbrain cells [Zhou & Freed 2005; Liu et al. 2008]. Moreover, knockdown of DJ-1 in human dopaminergic neuroblastoma cells decreases the

² The term 'isoform' is hereafter used to describe different posttranslational modified forms of one protein.

mRNA expression of genes involved in ROS removal, such as manganese superoxide dismutase, catalase and glutathione peroxidase 1 [Zhong & Xu 2008].

Furthermore, DJ-1 interacts with the inhibitors of various transcription factors, including the androgen receptor, p53 and the nuclear factor erythroid 2-related factor 2 (Nrf2) [Takahashi et al. 2001; Niki et al. 2003; Shinbo et al. 2005; Xu et al. 2005b; Clements et al. 2006; Zhong et al. 2006].

DJ-1 is also discussed as a molecular (co-)chaperone [Wilson 2011]. The chaperone activity thereby depends on the redox state as DJ-1 prevents the aggregation of several substrates *in vitro* only under oxidizing conditions [Shendelman et al. 2004] and the association of DJ-1 with mitochondrial Hsp70 is enhanced when cells are treated with H₂O₂ [Li et al. 2005]. DJ-1 has also been found in complex with alpha-synuclein [Meulener et al. 2005b] and, in a redox-dependent manner, prevents the abnormal aggregation of alpha-synuclein and neurofilament light subunits, two substrates found in Lewy body inclusions that are characteristic for PD [Shendelman et al. 2004; Zhou & Freed 2005; Zhou et al. 2006].

Moreover, DJ-1 interacts with the PI3K pathway in response to oxidative stress, a pathway that is also activated through insulin and leptin receptor signaling amongst others (see 1.2.2). This action is exerted via oxidation-dependent binding of DJ-1 to the phosphatase and tensin homologue (PTEN), an inhibitor of the PI3K pathway, whereby it promotes PKB phosphorylation [Kim et al. 2005a; Yang et al. 2005; Kim et al. 2009b; Aleyasin et al. 2010; Das et al. 2011].

DJ-1 inhibits several apoptotic pathways in response to oxidative stresses. First, DJ-1 competes with pro-caspase-8 to bind to the Fas-associated protein with death domain (FADD), an adaptor molecule of the death receptor [Fu et al. 2012]. Thereby procaspase 8 activation is repressed and the formation of the death-inducing signaling complex inhibited [Fu et al. 2012]. Second, DJ-1 represses the cleavage of caspase 3 induced by UV irradiation [Fan et al. 2008b] or hypoxia [Vasseur et al. 2009]. Third, UV irradiation increases the translocation of DJ-1 to mitochondria, where it binds to the anti-apoptotic Bcl-XL in an oxidation-dependent manner thereby preventing Bcl-XL degradation [Ren et al. 2011]. Fourth, DJ-1 suppresses JNK signaling through interacting with the mitogen-activated protein kinase kinase kinase 1 (MEKK1) [Mo et al. 2008; Pham et al. 2010]. JNK activity is increased by inflammatory processes e.g. such as induced by HF diet (see 1.2.2) and mediates apoptosis. Moreover, JNK can be activated by apoptosis signal-regulating kinase 1 (ASK1). DJ-1 inhibits ASK1 through (I) direct binding [Gorner et al. 2007; Waak et al. 2009], (II) sequestering the pro-apoptotic Death domain-associated protein 6 (DAXX) in the nucleus whereby DAXX is stopped from translocating to the cytoplasm and activating ASK1 [Junn et al. 2005; Karunakaran et al. 2007] or (III) by preventing the dissociation of the negative regulator thioredoxin from ASK1 [Im et al. 2010]. On the other hand, JNK can activate p53

transcriptional activity. DJ-1 can directly interact with p53 and thereby it decreases Bax expression [Fan et al. 2008b] providing another mechanism for protecting against apoptosis.

Furthermore, DJ-1 plays a role in mitochondrial integrity at several levels. First, DJ-1 is implied in the maintenance of the correct function of complex I of the respiratory chain. DJ-1 directly binds to the NDUFA4 and ND1 subunits of complex I and its colocalization with complex I is enhanced by oxidative stress [Hayashi et al. 2009]. Knockdown of *Dj-1* in a mouse embryonic fibroblast cell line, HEK293 cells or *Dj-1* null dopaminergic neurons lead to reduced complex I activity [Hayashi et al. 2009; Kwon et al. 2011]. Moreover, loss of *Dj-1* in mice, flies and *C. elegans* increases the vulnerability to mitochondrial complex I inhibition [Kim et al. 2005b; Meulener et al. 2005a; Ved et al. 2005]. Second, the H₂O₂ production is increased in isolated mitochondria from brain or skeletal muscle of *Dj-1*^{-/-} mice as well as in *Dj-1* knockdown mouse insulinoma cells [Andres-Mateos et al. 2007; Irrcher et al. 2010; Jain et al. 2012]. Increased ROS production of DJ-1 deficient mouse embryonic fibroblasts results in elevated mitochondrial permeability transition pore opening and reduced mitochondrial membrane potential as well as reduced ATP production [Andres-Mateos et al. 2007; Krebiehl et al. 2010; Giaime et al. 2012]. Third, *Dj-1*^{-/-} mice further show reduced expression of the two uncoupling proteins UCP4 and UCP5 in the substantia nigra and increased oxidation of matrix proteins [Guzman et al. 2010]. And fourth, DJ-1 deficient cultured neurons, mouse brain, lymphoblast and beta cells display an abnormal mitochondrial phenotype including fragmentation [Irrcher et al. 2010; Krebiehl et al. 2010; Jain et al. 2012]. The induced mitochondrial fragmentation can be rescued by the coexpression of DJ-1 in human neuroblastoma cells [Kamp et al. 2010].

As a last example, DJ-1 was proposed to be involved in autophagy, a process that has also been suggested to play a role in energy balance regulation (see 1.2.2). However, the exact function of DJ-1 in autophagy is unresolved since *Dj-1* silencing has been shown to upregulate [Vasseur et al. 2009; Irrcher et al. 2010; Ren et al. 2010; Thomas et al. 2011] but also downregulate autophagy [Gonzalez-Polo et al. 2009; Krebiehl et al. 2010]. It has been suggested that DJ-1 directly regulates upstream activators of autophagy including mTOR [Vasseur et al. 2009].

The list of biological functions of DJ-1 is not complete as it is also associated with fertility, tumorigenesis, and neurodegeneration amongst others (reviewed in da Costa [2007]; Kahle et al. [2009]). However, the reason for these multiple functions can be attributed to DJ-1's ability to interact with RNA as well as with numerous proteins, a feature that is influenced by changes in the redox state in many cases (Fig. 1-5 C). Consequently, DJ-1 has been termed a multifunctional oxidative stress response protein that functions in regulating cellular organelle homeostasis [Krebichl et al. 2010; Wilson 2011]. Thereby, it cross-talks with several

pathways, some of which are implicated in energy balance regulation and the development of obesity.

Fig. 1-5. DJ-1 constitutes a multifunctional oxidative stress responsive protein. (A) Post-translational modifications of DJ-1. In the presence of reactive oxygen species (ROS), DJ-1 is oxidized (Ox) at cysteine and/or methionine residues decreasing its isoelectric point (pI). DJ-1 can further be SUMOylated (SUMO). (B) The subcellular distribution of DJ-1 is dynamic. The major DJ-1 pool is located in the cytoplasm but nuclear and mitochondrial translocation can be enhanced in response to ROS. (C) DJ-1 interacts with numerous proteins involved in diverse biological processes. Several protein interactions can be influenced by changes in ROS levels or redox state. AR – androgen receptor. Nrf2 - nuclear factor erythroid 2-related factor 2. HSP70 – heat shock 70 kDa protein. PTEN - phosphatase and tensin homologue. PI3K - phosphatidylinositol-3-kinase. ASK1 - apoptosis signal-regulating kinase 1. DAXX - Death domain-associated protein 6. FADD - Fas-associated protein with death domain. MEKK1 - mitogen-activated protein kinase kinase kinase 1. JNK - serine/threonine kinase c-Jun-N-terminal kinase. Modified from Cookson [2003].

1.5 Aims and scope

It is well established that obesity is caused by disturbances in the neuronal control of energy balance and the hypothalamus is an important regulator of food intake and energy expenditure. We therefore investigated, whether alterations occur in the murine hypothalamic proteome in response to a short-term diet intervention. Indeed, several differentially expressed proteins emerged from the comparison of hypothalamic protein expression patterns between HF and control diet-fed mice. The most promising candidate, DJ-1, was followed up using two approaches: First, the responsiveness of DJ-1 to HF diet feeding was validated in the same mouse model focusing on the composition of the DJ-1 protein pool. Second, a *Dj-1* deficient mouse line was phenotypically and metabolically characterized under a HF diet challenge.

The present Ph.D. thesis arose within the framework of the NGFN-Plus network 'Molecular Mechanisms in Obesity' that targets the identification of polygenes predisposing to obesity and their subsequent evaluation under epidemiological, clinical, functional and therapeutic aspects. Complementary to the identification of new candidate genes in humans and mice, our strategy aimed to contribute towards the identification of new obesity candidates in mice on the protein level utilizing a discovery-oriented proteomics approach.

Potentially, the altered proteins represent candidates for studies in humans that cannot be detected via genome wide association studies. The relevance of these candidates could then be validated in human epidemiologic and obesity-specific study populations.

Viewed in a broader context, this work contributes to unravel the underlying molecular mechanisms in the central nervous system dealing with energy-balance regulation. The understanding of how energy homeostasis is shifted out of balance during the development of overweight might provide new insight into the susceptibility of humans to become obese and thus enables preemptive intervention.

2 METHODS

2.1 Animals

Studies were performed on mice bred in house³ and kept under specific pathogen-free conditions (with regular hygiene monitoring according to FELASA⁴ criteria) unless otherwise stated. Mice were housed in individually ventilated cages (IVC, type II, 540 cm²) and kept on a 12-hour light/dark cycle. Rooms were maintained at 22 ± 1°C with a relative humidity of 50-60 %. Mice were fed a standard chow diet (V1124) until assigned to the feeding experiments (see below). Diets were obtained from Ssniff Spezialdiäten GmbH, Soest, Germany (Appendix I.I Fig. A1). Procedures were carried out in accordance with the German animal welfare law and approved by the government of Oberbayern, Germany.

Short-term high-fat diet-feeding of three different inbred mouse strains for proteome analyses of hypothalami⁵

Seven-week-old male SWR/J, C57BL/6N or AKR/J mice were either fed a control (11 cal% fat, soybean oil; E15000-047) or a high-fat diet (40 cal% fat, palm oil; S0372-E712) for ten days (n = 5-6 per diet group). Mice were kept at the German Mouse Clinic, Munich, Germany and housed in groups of 3-4 animals per cage. Body mass was determined at the beginning and the end of the feeding period. The diet groups were matched for body mass. Body composition was measured in the abdominal part using micro computer tomography (LaThetaTM LCT-100, Aloka; obtained from Zinsser Analytic GmbH, Germany) after the 10-day challenge. Mice were killed by cervical dislocation before collection of hypothalami.

Short-term high-fat diet-feeding of mice for candidate validation experiments

Seven-week-old male C57BL/6N or AKR/J mice were either fed a control (12 cal% fat, soybean oil; S5745-E702) or a high-fat diet (48 cal% fat, soybean oil and palm oil; S5745-E712, HF) for two or ten days (Appendix I.I Fig. A1: diet composition). Mice were singly housed during the feeding period. Body mass and body composition via nuclear magnetic resonance (NMR) spectroscopy (Bruker) were measured at the beginning and the end of the feeding period. The diet groups were matched for body mass. Mice were euthanized with carbon dioxide before collection of plasma and tissues. Different cohorts were used for different follow-up experiments (Supplementary Table S1). In one cohort, 1 % N-

acetylcysteine (NAC, pH 7.2) was supplied in the drinking water. NAC water was changed twice and mice, food racks and water bottles were weight four times during the 10-day feeding period to assure an adequate water and food intake.

High-fat diet challenge of *Dj-1* deficient (*Dj-1*^{-/-}) mice

The *Dj-1* deficient mouse line (XE726 DJ-1) was kindly provided by Prof. Dr. Wolfgang Wurst (Helmholtz Zentrum München, Munich, Germany) for breeding in our facility. The mouse line was generated using the gene trap method [Pham *et al.* 2010]. Briefly, the gene trap vector (pGT1Lxf) containing a beta-galactosidase/neomycin fused gene was integrated between exon 6 and exon 7 of the murine *Dj-1* gene of the embryonic stem cell clone XE726. Clones were injected into blastocystes of C57BL/6J mice and resulting chimeras were crossed with C57BL/6J mice [Pham *et al.* 2010]. Mice derived from heterozygous breeding pairs after the mutation had been backcrossed 11 times onto C57BL/6J background. At four weeks of age, male and female *Dj-1*^{-/-} mice and wildtype littermates mice were assigned to either a control (12 cal% fat, soybean oil; S5745-E702) or a HF diet (48 cal% fat, soybean oil and palm oil; S5745-E712; Appendix I.I Fig. A1). Mice remained on the diet for 14 weeks. For a part of the animals, the feeding period was extended to 32 weeks. Every fortnight, mice were weight and fat and lean mass were determined using a NMR spectrometer (Bruker) which had been calibrated with mouse adipose tissue and chicken breast. Glucose tolerance, food intake, locomotor activity, energy expenditure and sensitivity towards leptin were measured during the last two weeks of the feeding periods in subgroups of animals (see below).

2.1.1 Genotyping of the *Dj-1* deficient mouse line

DNA was prepared from tail tips that were incubated in 500 µl tail buffer supplemented with 0.4 mg/ml Proteinase K (Fermentas) at 55°C until dissolved. DNA was precipitated with 500 µl isopropanol, washed with 70 % ethanol and dissolved in 40 µl nuclease-free water. Centrifugation steps were performed at 16000 g for 2-3 min at room temperature. A PCR was carried out according to Table 2-1 and 2-2 using the primers (5'-3') AGGCAGTGGAGAAGTCCATC (wildtype forward); AACATACAGACCCGGGATGA (wildtype reverse) and CGGTACCAGACTCTCCCATC (mutant reverse) yielding product sizes of 457 bp (wildtype) or 231 bp (mutant).

Tail buffer: 100 mM Tris, 5 mM EDTA, 0.2 % (w/v) SDS, 200 mM NaCl; pH 8.5

2.1.2 Intraperitoneal glucose tolerance test (i.p. GTT)

Animals were deprived of food for 6 hours (8 am to 2 pm). Fasting blood glucose levels (= 0 minutes) were measured from tail blood using a blood glucose meter (Abbott) with disposable test strips. Following i.p. injection of 2 mg glucose \cdot kg $^{-1}$ body mass, blood glucose was monitored after 15, 30, 60 and 120 minutes.

2.1.3 Food intake and locomotor activity measurements

Food intake and spontaneous locomotor activity was measured using a feeding-drinking-activity system (TSE Systems). Up to 16 animals were kept separately in type III cages (820 cm 2) with *ad libitum* access to food and water, while the consumption was automatically registered with a resolution of one data point per minute. Locomotor activity was recorded as counts of beam breaks of surrounding light barriers in X, Y and Z direction (Fig. 2-1). Activity can be differentiated into ambulatory (beam breaks of two consecutive light barriers) or fine movement (successive beam breaks of the same light barrier). Mice were accustomed to the system for one day. Energy intake (kJ) was calculated from food intake and energy content of the diet and expressed per 24 hours or per dark phase. Only the dark phases were analyzed for activity parameters. Data of 2-3 days or nights were averaged. If the intra-individual coefficient of variation exceeded 33 % (for energy intake) or 40 % (for activity), mice were excluded to increase the statistical power.

Fig. 2-1. Feeding-drinking-activity system. Individual cages are surrounded by sensor frames containing emitter and receiver diodes. Diodes of the Z-frame are located above the Y-frame. Counts of beam breaks of the X- and Y-frame constitute horizontal activity, counts of beam breaks of the Z-frame refer to rearing activity. Food was supplied in one basket.

2.1.4 Energy expenditure measurement (indirect calorimetry)

The chemical energy of nutrients is utilized by the body through oxidation, whereby oxygen is consumed and carbon dioxide and water are produced. The metabolic rate indicates the rate at which chemical energy is converted into heat and external work and is most commonly measured indirectly as the oxygen consumption rate [Hill et al. 2012]. During indirect calorimetry, the energy expenditure is determined by means of the caloric equivalent indicating the energy per liter oxygen consumed which ranges from 19-21 kJ·l O₂⁻¹ depending on the oxidized substrate.

Indirect calorimetry was performed using the LabMaster system from TSE Systems, Bad Homburg, Germany. Up to eight animals were kept separately in modified home cages and placed in a temperature-controlled climate chamber (Feutron®). With a constant flow rate of 0.7 l·min⁻¹ air was pulled from the cages and volumes of oxygen consumed ($\Delta\text{vol}\% \text{O}_2$) and carbon dioxide produced ($\Delta\text{vol}\% \text{CO}_2$) were determined once every 9 min. For three days, animals were measured with *ad libitum* access to food and water at $21.5 \pm 0.5^\circ\text{C}$. The oxygen consumption rate ($\dot{V}\text{O}_2$) was calculated according to the following equation [Heldmaier & Ruf 1992]:

$$\dot{V}\text{O}_2 [\text{ml}\cdot\text{h}^{-1}] = \Delta\text{vol}\% \text{O}_2 * \text{flow} [\text{l}\cdot\text{h}^{-1}] * 10.$$

The carbon dioxide production rate ($\dot{V}\text{CO}_2$) was calculated accordingly:

$$\dot{V}\text{CO}_2 [\text{ml}\cdot\text{h}^{-1}] = \Delta\text{vol}\% \text{CO}_2 * \text{flow} [\text{l}\cdot\text{h}^{-1}] * 10.$$

The respiratory exchange ratio (RER) was calculated according the equation:

$$\text{RER} = \dot{V}\text{CO}_2 [\text{ml}\cdot\text{h}^{-1}] / \dot{V}\text{O}_2 [\text{ml}\cdot\text{h}^{-1}].$$

The RER differs between carbohydrates (1.0), proteins (0.81) and lipids (0.705) and thus is indicative for the substrate oxidized for energy generation [Even & Nadkarni 2012]. As a measure of energy expenditure, heat production (HP) was calculated according to Heldmaier [1975]:

$$\text{HP}_{22^\circ\text{C},ad-lib} [\text{mW}] = (4.44 + 1.43 * \text{RER}) * \dot{V}\text{O}_2 [\text{ml}\cdot\text{h}^{-1}],$$

whereby $\dot{V}\text{O}_2$ corresponds to the sum of the hourly means over 24 hours and RER corresponds to the daily mean. For the final result the mean HP of day 2 and 3 were averaged. On the fourth day, food was removed in the morning and temperature was set to $30 \pm 0.5^\circ\text{C}$ (thermoneutral zone) [Meyer et al. 2004]. During the following 6 hours, the basal metabolic rate (BMR) was determined as the minimal $\dot{V}\text{O}_2$ of data smoothed over 20 min with a coefficient of variation below 5 %. HP under thermoneutral, postabsorptive conditions ($\text{HP}_{30^\circ\text{C},pa}$) was calculated from BMR and the corresponding RER. HP was normalized to the sum of lean mass + 0.2 * fat mass [g] [Even & Nadkarni 2012] whereby lean and fat mass was determined shortly before the experiment using NMR spectroscopy (Bruker). Mice and food racks were weighed daily.

2.1.5 Determination of sensitivity towards intraperitoneally administered leptin

The food intake in response to an intraperitoneal (i.p.) leptin injection was used as a physiological marker for leptin sensitivity. Mice were accustomed to the feeding-drinking-activity system (TSE Systems) for at least 24 hours. On three consecutive days, mice received i.p. injections of PBS followed by $5 \text{ mg}\cdot\text{kg}^{-1}$ body mass mouse leptin⁶ (solved in PBS) the day after. The leptin dose was chosen according to Münzberg et al. [2004]. Injections were given shortly before the onset of the dark phase. Food intake was measured automatically throughout the whole experiment. Body mass of mice was surveyed daily.

⁶ Leptin was kindly provided by Prof. Dr. Arne Skerra, TU München, Freising, Germany.

2.1.6 Tissue dissection

At the end of the feeding periods, mice were euthanized with carbon dioxide. For dissection of the hypothalamus, sacrificed mice were decapitated. The brain was quickly removed and placed in a custom-made brain blocker with the ventral side facing up (Fig. 2-2 A). The about 3-mm-thick coronary section containing the hypothalamus was dissected and the hypothalamus was cut out of this section with a preformed metal punch. For collection of the ventral part of the hypothalamus containing the arcuate nucleus, the hypothalamus was divided in the horizontal plane into two parts of approximately the same size (Fig. 2-2 B). Samples termed ‘forebrain’ refer to the remaining tissue after removing the hypothalamus, cerebellum, brainstem, and olfactory bulbs. Left and right posterior subcutaneous (psWAT) and epididymal (eWAT) or periovarial white adipose tissue depots (poWAT) as well as gastrocnemius muscles (M. gastroc) were combined. Collected tissues were frozen in liquid nitrogen and stored at -80°C .

Fig 2-2. Dissection of mouse hypothalamus. (A) The brain was placed in the brain blocker with the ventral side facing up. The coronal section between the two incisions containing the hypothalamus (dashed box) was cut out using a razor blade. (B) From this section, the hypothalamus (dashed box) was dissected with a metal punch. For collection of the ventral hypothalamus, the hypothalamus was divided in the horizontal plane (dashed line).

2.2 Plasma glucose, insulin and leptin level determination

After euthanization with carbon dioxide, cardiac blood was collected from non-fasted mice in a heparin-coated tube and centrifuged for 5 min at 2000 *g*. The time window of blood collection did not exceed 3.5 hours during the day time. The supernatant was frozen in liquid nitrogen and stored at -80°C . Plasma glucose was determined using a blood glucose meter (Abbott). Plasma insulin levels were measured by ELISA (Mercodia) in samples diluted 1:5. Insulin sensitivity was estimated from glucose and insulin levels applying the homeostatic model assessment of insulin resistance ($\text{HOMA-IR} = (\text{insulin } [\mu\text{U/ml}] * \text{glucose } [\text{mmol/l}]) * 22.5^{-1}$) [Hoeks *et al.* 2011]. Plasma leptin levels were determined by ELISA (BioVendor).

2.3 Glutathione assay

Reduced (GSH) and oxidized (GSSG) glutathione were measured with a kit based on an enzymatic recycling method (Cayman) according to the manufacturer's instructions. Samples were prepared according to Rahman *et al.* [2006]. In short, frozen tissue was grinded in liquid nitrogen and a part of the tissue powder was homogenized in 5 ml*g⁻¹ potassium phosphate buffer (pH 7.5) supplemented with 5 mM EDTA, 0.1 % Triton X-100, 0.6 % sulfosalicylic acid and centrifuged for 10 min at 8000 g (4°C). Protein concentration of the supernatant was determined by Bradford assay.

2.4 Western blot analysis

Frozen tissue was homogenized in lysis buffer 1. Forebrain, muscle and WAT samples were grinded in liquid nitrogen using mortar and pestle prior to homogenization. Homogenates were treated in an ultrasonic bath for 1 min, centrifuged at 16000 g for 15 min (4°C) and supernatants were collected. Precipitates were resuspended in lysis buffer 1 and the procedure repeated. Supernatants were combined. Protein concentrations were assayed according to Bradford. A defined amount of protein per sample was separated according to the molecular weight via sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) based on the discontinuous Laemmli system [Laemmli 1970] in a vertical electrophoresis system (Bio-Rad). Separated proteins were transferred from SDS gels onto nitrocellulose membranes (LI-COR Biosciences) using either a semi-dry system (Bio-Rad) with 0.8 mA*cm⁻² for 45 min or, in case of OXPHOS immunoblots, a tank system (Bio-Rad) with 100 V for 1 h. After blocking for 1 h with 3 % BSA in TBS, immunoblots were incubated with primary antibody solution in TBST over night at 4°C (Appendix I.II Table A1: Primary antibodies). Afterwards, membranes were incubated for 1 h with infrared dye-conjugated secondary antibody solution (1:20 000, LI-COR Biosciences) in TBST at room temperature. Target proteins were detected using the Odyssey[®] Infrared Imaging System (LI-COR Biosciences).

Lysis buffer 1 30 mM Tris, 2 M thiourea, 7 M urea, 4 % (w/v) CHAPS, 1 % (w/v) DTT, 1 % (v/v) protease and phosphatase inhibitor cocktail (Sigma-Aldrich); pH 8

TBS 0.02 M Tris (pH 7.6), 0.137 M NaCl

TBST TBS + 1% (v/v) Tween[®] 20

2.5 Protein concentration determination according to Bradford

Protein concentrations were assayed in duplicates in 96-well plates using the Roti[®]-Quant solution (Carl Roth) according to the manufacturer's protocol. For the standard curve, BSA concentrations of 0, 0.02, 0.04, 0.06, 0.08 and 0.1 mg*ml⁻¹ were used. Samples and standards were diluted in distilled water. Absorbance at 590 nm was measured using a microplate reader (Tecan).

2.6 Proteome analysis of hypothalami from high-fat or control diet-fed mice

Proteome analysis was carried out by Dr. Gereon Poschmann from the group of Prof. Dr. Kai Stühler, Molecular Proteomics Laboratory (MPL), Heinrich-Heine-Universität Düsseldorf, Germany [Poschmann *et al.*, *in preparation*]. In short, hypothalamic protein expression patterns between HF and control diet groups were compared independently for each strain using two-dimensional difference gel electrophoresis (2D-DIGE) and differential proteins were identified by mass spectrometry. For this, frozen hypothalami were homogenized in lysis buffer 2 as described in Chapter 2.4. Proteins were labeled with fluorescent CyDyes (GE Healthcare, minimal labeling). One HF/control pair of animals was analyzed in one gel together with an internal standard prepared as a pool of all samples from one mouse strain. Carrier ampholyte isoelectric focusing (first dimension) was carried out in tube gels, after which proteins were separated in the second dimension by 15.2 % acrylamide/1.3 % bisacrylamide SDS gels [Klose & Kobalz 1995; Poschmann *et al.* 2012]. Gels were scanned on a Typhoon Trio laser scanner (GE Healthcare) and gel images were processed by the DeCyder-2D-V6.5 software suite (GE Healthcare) run in batch mode. For spot detection the estimated spot number was set to 10 000 and spots < 20 000 arbitrary units were removed. Spots were matched across the gels and normalized to the internal standard. Only spots matched in at least 4 gels, showing a ratio between HF and control diet of < 0.8 or > 1.25 and a p-value < 0.05 (two-sided Student's t-test performed on log-transformed data) were considered.

Protein spots found to be differentially abundant between HF and control diet-fed mice were manually excised from the preparative gel and in-gel digested with trypsin (Promega) in 10 mM ammonium bicarbonate buffer (pH 7.8) at 37°C overnight. Tryptic peptides were extracted twice with acetonitrile/ 5 % formic acid (50:50, v/v), acidified by addition of 5 % formic acid after removal of acetonitrile and subjected to nano-HPLC-ESI tandem mass spectrometry (Appendix II). Peptides and proteins were identified using MASCOT 2.4.1

software and the UniProtKB database release 12/2012 with shuffled decoy version of all entries.

Lysis buffer 2 30 mM Tris-HCl, 2 M thiourea; 7 M urea; 4 % CHAPS (w/v); pH 8.0

2.7 Separation of DJ-1 isoforms by isoelectric focusing (IEF) followed by immunodetection

For the separation of proteins based on their isoelectric point (pI) with subsequent immunodetection of DJ-1 two different methods were applied:

(I) Gel-based IEF followed by western blotting

This method was carried out by Dr. Gereon Poschmann from the group of Prof. Dr. Kai Stühler, Molecular Proteomics Laboratory (MPL), Heinrich-Heine-Universität Düsseldorf, Germany [Poschmann *et al.*, *in preparation*]. IEF was performed as described in Chapter 2.6 applying 50 µg of unlabeled protein. The gel was incubated for 20 min in 125 mM Tris, 40 % (w/v) glycerin, 65 mM DTT and 104 mM SDS and the proteins were transferred onto a nitrocellulose membrane using a semi-dry system. Subsequently, the membrane was probed with a rabbit monoclonal anti DJ-1 antibody (1:2000, Biomol, #2398-1). The target was detected with an IRDye 800-conjugated anti-rabbit antibody (1:15 000, LI-COR Biosciences, #926-32213) using the Odyssey[®] Infrared Imaging System (LI-COR Biosciences) or an Alexa Fluor 555-conjugated anti-rabbit antibody (1:5000, Life Technologies, #A21429) in combination with a Typhoon 9400 Scanner (GE Healthcare). Protein isoforms were quantified using the gel analyzer plug-in of the ImageJ 1.45s software [Schneider *et al.* 2012].

(II) Capillary IEF immunoassay

This method was carried out by Dr. Daniela Besong Agbo and Dr. Hans Klafki from the group of Prof. Dr. Jens Wiltfang, LVR-Klinikum Essen, Germany [Besong Agbo *et al.* 2013]. The assay was performed on a NanoPro[™] 1000 Instrument (Protein Simple, Santa Barbara, CA, USA). Briefly, lysates were prepared as described in Chapter 2.6, denatured (40 mM DTT, 9 M urea) and mixed 1:2 with an ampholyte premix (separation gradient pH 5-8) containing a fluorescent pI standard ladder and a protease and phosphatase inhibitor mix. Samples, primary antibody targeting DJ-1 (1:50, Biomol, #2398-1), biotinylated anti-rabbit antibody, streptavidin-horseradish peroxidase conjugate (1:100, Protein Simple), and luminol/peroxide

mix were loaded on a 384-well plate and transferred to the NanoPro™ 1000 instrument. The automatically run assay was programmed with the Compass software (Protein Simple, version 1.3.7). Capillaries were loaded with 400 nl sample solution and IEF was performed at 21 mW for 40 minutes. Afterwards, analytes and standards were immobilized to the capillary wall by applying UV-light for 100 seconds followed by incubations with primary DJ-1 antibody (120 min), biotinylated anti-rabbit antibody (60 min), streptavidin-horseradish peroxidase conjugate (120 min) and luminol/peroxide mix (30 to 960 seconds). Peak integration and pI marker calibration for peak alignment were performed using Compass software.

2.8 Isolation of mitochondria and cytosolic fraction from brain tissue for analysis of DJ-1 localization

Brains without olfactory bulbs, brain stem and cerebellum were placed in icecold isolation buffer, cut into smaller pieces using scissors and cleaned from blood. The tissue was homogenized in 5 ml isolation buffer in a 15-ml glass-glass homogenizer with 12 strokes and centrifuged at 1300 *g* for 6 min at 4°C in a 50-ml centrifuge tube precipitating crude cell debris and nuclei (pellet P1, Fig. 2-3 A). The supernatant was transferred into a new centrifuge tube and centrifuged at 13000 *g* for 10 min at 4°C separating a crude mitochondrial fraction. The supernatant was transferred into a 12-ml ultracentrifuge tube for further centrifugation at 100000 *g* for 1 h (4°C). The obtained supernatant is referred to as cytosolic fraction to which 2.5 $\mu\text{l}\cdot\text{ml}^{-1}$ protease inhibitor and phosphatase inhibitor cocktail (Sigma-Aldrich) were added, respectively. The pellet represents the microsomal fraction containing ER and other membranes [Darios *et al.* 2003]. The crude mitochondrial fraction was resuspended in 500 μl 20 μM Na_2CO_3 in 25 mM HEPES buffer (pH 7.5) and incubated for 30 min on ice to detach loosely associated proteins from the mitochondria [Blackinton *et al.* 2009]. Mitochondrial suspension was ultracentrifuged at 60000 *g* for 30 min (4°C). Precipitated mitochondria were washed once in isolation buffer and resuspended in 250 μl isolation buffer (Fig. 2-3 A). Protease and phosphatase inhibitor cocktails (10 $\mu\text{l}\cdot\text{ml}^{-1}$, Sigma-Aldrich) were added to mitochondria and mitochondrial supernatant. Protein concentrations were determined by the Bradford method (Chapter 2.5). The purity of the different fractions was analyzed by immunodetecting cell organelle specific markers (Fig. 2-3 B).

Isolation buffer 215 mM mannitol, 75 mM sucrose, 20 mM HEPES, 1 mM EGTA; pH 7.2

Fig. 2-3. Preparation of subcellular fractions from mouse brain tissue. (A) Flow chart showing the preparation steps of mitochondrial and cytosolic fractions. **(B)** Western blot targeting specific markers for individual cell organelles: Histone H3 (nucleus), peroxisomal membrane protein 70 (PMP70, peroxisomal membrane), voltage-dependent anion channel (VDAC, outer mitochondrial membrane), cytochrome c oxidase subunit 4 (COXIV, inner mitochondrial membrane), superoxide dismutase 2 (SOD2, mitochondrial matrix).

2.9 Characterization of isolated brain mitochondria from HF or control diet-fed mice

For functional characterization of mitochondria, the crude mitochondrial fraction was isolated from brain tissue according to Chapter 2.8 with the following modifications: use of a 15-ml glass-teflon homogenizer with 7 to 8 strokes, addition of 0.1 % fatty-acid free BSA to the isolation buffer and resuspension of mitochondria in 500 μ l KHE buffer (see Chapter 2.9.1).

2.9.1 Oxygen consumption measurements of isolated mitochondria using a Clark electrode

The Clark electrode (Rank Brothers) consists of a platinum cathode and a silver anode that are surrounded by 3 M KCl and separated from an incubation chamber by an oxygen permeable Teflon membrane. The platinum cathode is polarized with -0.6 V relative to the silver anode. Under this condition, the oxygen partial pressure inside the incubation chamber is proportional to the electric current between anode and cathode (Fig. 2-4) which is amplified (PowerLab 26T, ADInstruments) and recorded by the Labchart 5 software.

Fig. 2-4. Redox reaction inside the Clark electrode. Oxidation occurs at the silver anode, reduction at the platinum cathode.

The electrode was calibrated with sodium dithionite in KHE buffer (0 μM O_2) and air saturated KHE buffer (240 μM O_2). Measurements were carried out with 500 μg mitochondrial protein in 1 ml air saturated KHE buffer at 37°C under continuous stirring (level 6). As substrate, either 5 mM succinate or a combination of 5 mM glutamate and 5 mM malate was used (in H_2O , pH 7). After closing the incubation chamber, 8 μM rotenone (in ethanol, only for succinate respiration) followed by substrate, 1 mM ADP (in H_2O , pH 7), 2 $\mu\text{g}\cdot\text{ml}^{-1}$ oligomycin (in ethanol) and 2.5 μM FCCP (in DMSO) were added in 1.5-min intervals using a Hamilton syringe. Oxygen consumption rates under the different conditions were determined from the recorded slopes and expressed as $\text{nmol O}_2\cdot\text{min}^{-1}\cdot\text{mg protein}^{-1}$. The respiratory control ratio (RCR) was calculated by dividing the oxygen consumption rate in the presence of substrate and ADP (state 3 respiration) by the oxygen consumption rate in the presence of substrate only (state 4 respiration). The RCR provides a measure of mitochondrial integrity by indicating the fold increase of respiration under phosphorylating conditions relative to non-phosphorylating respiration under substrate excess.

KHE buffer 120 mM KCl, 3 mM HEPES, 1 mM EGTA, 5 mM KH_2PO_4 , 0.3 % fatty-acid free BSA; pH 7.2

2.9.2 Mitochondrial membrane potential ($\Delta\Psi_m$) measurements in isolated brain mitochondria using Safranin O

The method utilizes the cationic membrane-permeant fluorescent dye Safranin O that accumulates inside energized mitochondria where its fluorescence is quenched due to a spectral shift [Akerman & Wikstrom 1976]. The relative decrease of the total fluorescence with hyperpolarization is considered to be proportional to the membrane potential [Toime & Brand 2010]. Measurements were performed in 96-well plates (FLUOTRACTM 200, Greiner Bio-One) at 37°C in triplicates. Fluorescence was measured at 495 nm excitation and 586 nm emission wavelength in a microplate reader (Tecan). In a final volume of 200 μ l/well, 100 μ g of mitochondrial protein, 2 μ M rotenone and 8 μ M Safranin O were combined in KHE buffer and measured over 30 min. Subsequently, mitochondria were energized by the injection of substrate (5 mM succinate or a combination of 5 mM glutamate and 5 mM malate) and measured for further 30 min before adding the artificial uncoupler FCCP (0.3 μ M). The resulting time course of fluorescence intensities is expressed in percent defining the last time-point prior to substrate injection as 100 % to adjust for different baseline levels of the samples. The maximal decrease of Safranin O fluorescence after the addition of substrate was calculated as a measure of membrane potential.

2.9.3 Detection of mitochondrial superoxide production using Amplex[®] Red

Superoxide ($O_2^{\cdot-}$) produced by isolated mitochondria is converted to hydrogen peroxide by superoxide dismutase (SOD). Horseradish peroxidase subsequently reduces H_2O_2 to water oxidizing the non-fluorescent dye Amplex[®] Red (Invitrogen) into the fluorescent resorufin (Fig. 2-5) [Zhou et al. 1997].

Fig. 2-5. Indirect detection of mitochondrial superoxide ($O_2^{\cdot-}$) production using Amplex[®] Red. HRP - Horseradish peroxidase. SOD - Superoxide dismutase.

Measurements were performed in 96-well plates (FLUOTRACTM 200, Greiner Bio-One) at 37°C in triplicates. Fluorescence was measured at 560 nm excitation and 590 nm emission wavelength in a microplate reader (Tecan). In a final volume of 200 µl/well, 50 µg of mitochondrial protein, 0.4 U SOD, 1.2 U HRP and 50 µM Amplex[®] Red were combined in KHE buffer with or without 2 µM rotenone. Fluorescence intensity was detected over 30 min with injection of 5 mM succinate or a combination of 5 mM glutamate and 5 mM malate after 10 min. From the resulting time course, for each sample the increase of the slopes before and after the addition of substrate was calculated and divided by the slope of the standard curve and the protein amount (Fig. 2-6). DMSO and ethanol solvent controls were run simultaneously. For the standard curve, 50 µg of mitochondria were inactivated by three freeze-thaw cycles. A point measurement was carried out in the reaction mixture described above supplemented with 0, 1, 2, 3, 4 and 5 nmol H₂O₂ in duplicates.

$$\text{H}_2\text{O}_2 \text{ production } [\text{nmol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}] = \frac{\text{slope}_{\text{substrate}} [\text{RFU} \cdot \text{min}^{-1}] - \text{slope}_{\text{no substrate}} [\text{RFU} \cdot \text{min}^{-1}]}{\text{slope}_{\text{standard}} [\text{RFU} \cdot \text{nmol}^{-1}] * m_{\text{mitochondria}} [\text{mg}]}$$

Fig. 2-6. Calculation of the H₂O₂ production rate.

2.10 RNA isolation from hypothalamic tissue

For isolation of total RNA, a complete or ventral hypothalamus was homogenized in 800 µl TRIsure (Bioline) for 20 s using an Ultra-Turrax (IKA), incubated for 5 min at room temperature, mixed with 160 µl chloroform, incubated for further 3 min and centrifuged for 15 min at 12000 g at 4°C. The clear top phase was mixed with 500 µl 75 % ethanol, transferred to columns of the SV Total RNA Isolation System (Promega) and proceeded according to the manual. RNA was eluted in 60 µl nuclease-free water and concentration was measured spectrophotometrically (Infinite[®] 200 NanoQuant, Tecan). For quality assessment, 2 µl of isolated RNA were mixed with 8 µl RNA loading buffer, incubated at 65°C for 10 min and separated by size on a denaturing formaldehyde agarose gel (1 %) for ~40 min at 100 V to visualize the 28S and 18S rRNA bands. RNA was stored at -80°C.

RNA loading buffer	200 µl formamide, 64 µl 37 % formaldehyde, 40 µl 10x MOPS, 8 µl H ₂ O, 8 µl ethidium bromide
Formaldehyde agarose gel	1 g agarose in 72 ml H ₂ O, 10 ml 10x MOPS buffer, 18 ml 37 % formaldehyde
10x MOPS buffer	400 mM MOPS, 100 mM sodium acetate, 10 mM EDTA; pH 7

2.11 Quantitative real-time polymerase chain reaction (qRT-PCR)

Isolated hypothalamic RNA was reverse-transcribed into cDNA using the QuantiTect[®] Reverse Transcription Kit (Qiagen) utilizing oligo-dT and random primers in a 10 μ l reaction mixture containing 500 ng RNA. The cDNA was stored at -20°C. Primer sequences (Appendix I.III Table A2) were designed using the Primer3 algorithm (SDSC Biology Workbench). Primer sequences were tested in a non-quantitative PCR and only primer pairs that generated a single, sharp product band were applied in the qRT-PCR analysis. For analysis of gene expression, the SYBR Green-based qRT-PCR was performed either on 96-well (Mastercycler[®] ep realplex egradient S, Eppendorf) or 384-well format (Roche LightCycler[®] 480) according to table 2-3 and 2-4. A melting curve was recorded at the end of the program to confirm the quality of the amplified product and identify possible non-specific reaction products.

Table 2-3. qRT-PCR reaction mixture for analysis of gene expression.

	Volume per reaction [μ l]	
	96-well	384-well
Sensimix SYBR NoRox (Bioline)	12.5	6.25
Primer forward	1.0 (10 pmol/l)	1.0 (5 pmol/l)
Primer reverse	1.0 (10 pmol/l)	1.0 (5 pmol/l)
Nuclease-free water	9.5	3.25
cDNA	1.0	1.0
Total	25.0	12.5

Table 2-4. qRT-PCR program for analysis of gene expression.

Step	Temperature [°C]	Time [s]	Cycles
Initialization	95	600	
Denaturation	97	10	} 45 x
Annealing	52	15	
Elongation	72	20	
Melting curve	60 to 95	1200	

Gene expression levels of the samples were calculated from a standard curve that was generated from pooled cDNA of all samples ($n = 12$) and diluted by 2^n in 8 steps. Standards were measured in duplicates. Sample cDNAs were diluted 1:10 to 1:50 and measured in triplicates. The mean expression of the technical replicates was normalized by the mean expression of *Heat shock protein 90 (Hsp90)* that was selected as housekeeping gene.

2.12 Transcriptome analysis of ventral hypothalamus comparing high-fat or control diet-fed *Dj-1*^{-/-} and *Dj-1*^{+/+} mice

Transcriptome next generation sequencing (RNA-Seq) was carried out by Dr. Karol Szafranski and Dr. Marco Groth from the group of Dr. Matthias Platzer, Fritz Lipmann Institute Jena, Germany. RNA of ventral hypothalami was isolated as described in Chapter 2.10 and the integrity was assessed using a RNA 6000 Nano chip (Agilent, Santa Clara, CA, USA). RNA-Seq was performed on the Illumina HiSeq 2000 platform (Illumina, San Diego, CA, USA). RNA-Seq libraries were prepared using TruSeq RNA Sample Prep kit v2, pooled to up to 7 libraries per lane and sequenced 50 nt single-sided (plus barcode) using TruSeq SBS kit v3-HS to result in a depth of at least 25 million read pairs per sample. Primary data was processed using CASAVA version 1.8.2.

Gene expression analysis

Next generation sequencing reads were mapped to the mouse genome (Genomatix Mining station; Genomatix, Munich, Germany) applying the library version NCBI build 37 and the EIDorado Version 08-2011 (seed mapping type 'deep', 92 % minimum alignment quality). Only unique hits (> 82 % of total hits) were subjected to differential expression analysis utilizing the Genomatix Genome Analyzer. Two groups were compared at once using both DESeq 1.10.1 and edgeR 3.0.4 algorithms, respectively. The p-value threshold was set to 0.05 with the use of a multiple testing correction introduced by Benjamini & Hochberg [1995]. A fold change of $\log_2 \geq 0.263$ indicated upregulation and $\log_2 \leq -0.263$ downregulation in the 'treated' vs. the 'control' group corresponding to a fold change of 1.2 or -1.2, respectively. Only differentially expressed genes found significant with both DESeq and edgeR algorithms and displaying a minimal expression level of 10 reads for the majority of animals in one group were considered.

Additionally, we performed a t-test statistic with log-transformed normalized expression (NE) values of the individual transcripts ($\log(\text{NE}+1)$). Genes for which at least one transcript was found different between two groups with a significance level of $p < 0.01$ and a mean NE fold change of $\log_2 > 0.263$ (upregulation) or $\log_2 < -0.263$ (downregulation), corresponding to a fold change of 1.2 or -1.2, respectively, were subjected to a pathway analysis using the Genomatix Pathway System.

2.13 Mitochondrial genome copy number quantification in mouse tissue

Frozen forebrain, gastrocnemius muscle and eWAT samples were grinded in liquid nitrogen using mortar and pestle. DNA was isolated from powdered tissue using the Wizard SV Genomic DNA Purification System (Promega) according to the manufacturer's protocol. DNA concentrations were measured spectrophotometrically (Infinite[®] 200 NanoQuant, Tecan) and diluted to 40 ng/μl with nuclease-free water.

The mitochondrial genome copy number is quantified relative to the nuclear genome copy number and provides a measure for mitochondria per cell. This is achieved by a qRT-PCR directed against targets exclusively found in the murine nuclear or mitochondrial genome (Table 2-5)⁷. The qRT-PCR was performed in a Roche LightCycler[®] on 96-well plates according to table 2-6 and 2-7 in duplicates. As a result, the relative DNA amount for each replicate was obtained according to the following equation:

$$\text{DNA [AU]} = 10^6 * (2^{\text{Cp}})^{-1}; \text{AU} - \text{Arbitrary Unit, Cp} - \text{Crossing point.}$$

Subsequently, the quotient of the mean mitochondrial DNA amount and the mean nuclear DNA amount was calculated.

Table 2-5. Primer-probe pairs for quantification of mitochondrial genome copy number designed for the Roche LightCycler[®].

2.14 Statistics

For comparison of two groups, significance was determined using two-sided Student's t-test with a p-value < 0.05 indicating significant differences. A Bonferroni correction was conducted manually for multiple comparisons by dividing the significance level by the number of comparisons. Equal variances were tested applying F-tests.

The phenotypic data of HF or control diet-fed *Dj-1^{-/-}* and *Dj-1^{+/+}* mice was analyzed by two-way ANOVA inclusive of testing for genotype:diet interactions. Male and female mice were regarded separately. ANOVA analysis was followed by post-hoc Bonferroni correction. Differences with $p < 0.05$ were considered significant. In case the data was not normally distributed, a log-transformation was performed. Analysis of covariance (ANCOVA) was performed to adjust fat and lean mass, respectively, to the mean body mass of each diet group. For this, fat or lean mass was plotted against body mass. From the linear regression functions for the diet-genotype groups, the predicted fat or lean mass was calculated from the body mass of individual animals as well as the mean body mass per diet group. Residuals were calculated for each animal and added to the predicted fat or lean mass of the diet group. Residuals were tested for normality using the Shapiro-Wilk test.

Whiskers of box plots indicate the minimum and maximum value, respectively.

T-tests and ANCOVA analysis were performed using Microsoft Office Excel 2007. Two-way ANOVA was performed using the software GraphPad PRISM 4 or SigmaPlot 12.3.

3 RESULTS

3.1 Alterations in the hypothalamic proteome associated with a short-term high-fat diet intervention

We aimed to detect alterations in the murine hypothalamic proteome in response to a short-term high-fat (HF) diet. Three inbred mouse strains with different susceptibility to diet-induced obesity (DIO) were compared: the obesity-prone AKR/J and C57BL/6N mice and the SWR/J mice that are resistant to DIO [Hesse *et al.* 2010]. Male 7-week-old mice of each strain were fed a HF or a control diet for 10 days. After this time, the body mass of HF diet-fed AKR/J and C57BL/6N mice was significantly increased compared to mice maintained on control diet (Fig. 3-1). This was due to elevated body fat as well as lean mass with a more pronounced level of DIO in AKR/J mice. In SWR/J mice, only very mild DIO was detectable as indicated by an increased fat mass (Fig. 3-1).

Fig. 3-1. Body mass, fat and lean mass of AKR/J, C57BL/6N and SWR/J mice after 10 days of HF or control diet. Mice were male and 7 weeks old ($n = 5-6$). Fat and lean mass were assessed in the abdominal part via Micro-CT. ANOVA indicated significant effects for diet and strain for body mass, fat and lean mass ($p < 0.001$) and a significant strain:diet interaction for body mass ($p = 0.001$) and fat mass ($p < 0.001$). Bonferroni posttest: *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$ HF vs. control diet-fed mice.

After 10 days of HF or control diet, hypothalami were dissected and protein expression patterns between the diet groups were compared within each strain using two-dimensional difference gel electrophoresis (2D-DIGE). Protein spots showing differential abundance between HF and control diet-fed mice were excised and mass spectrometrically identified. In AKR/J mice, 7 differentially abundant proteins were found, 6 in C57BL/6N and 3 in SWR/J mice with HF/control ratios ranging from 0.6 to 2.0 (Table 3-1). Thus, the number of HF diet-regulated proteins within a strain seems to correlate positively with the level of adiposity.

Table 3-1. Alterations in the hypothalamic proteome induced by a 10-day HF feeding in AKR/J, C57BL/6N and SWR/J mice. HF and control diet-fed mice were compared within each strain using 2D-DIGE. Listed are spots with significantly differential volumes that were identified by nano-HPLC-ESI tandem mass spectrometry.

*Ratio of normalized and standardized 2D-DIGE spot volumes. Data generated by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

Strikingly, the protein DJ-1 (PARK7) was found to be more abundant in the HF groups of all strains as compared to the respective control groups (Fig. 3-2) and was thus chosen for validation.

Fig. 3-2. 2D-DIGE spot volumes of the spot identified as DJ-1. Data points represent individual animals. Student's t-test: ***p < 0.001.

3.2 High-fat feeding alters the isoform composition of the DJ-1 pool

3.2.1 The DJ-1 pool shifts towards more acidic isoforms in the brain upon high-fat feeding

Total protein expression and *Dj-1* transcript levels in hypothalami were comparable between HF or control diet-fed C57BL/6N mice (Fig. 3-3). Due to post-translational modifications, the intracellular DJ-1 protein pool comprises multiple isoforms varying in their isoelectric point (pI) [Natale et al. 2010]. The above result was obtained after hypothalamic protein homogenates were separated two-dimensionally by the isoelectric point (pI) in the first dimension and molecular weight in the second. Accordingly, the higher abundance of DJ-1 in HF animals likely represents only one specific DJ-1 isoform. We therefore investigated, whether the composition of the DJ-1 pool changes upon HF feeding. In order to quantify the different DJ-1 pI isoforms, we separated hypothalamic extracts via gel-based isoelectric focusing (IEF) with subsequent membrane transfer and DJ-1 immunodetection. With this approach, a total of 7 DJ-1 isoforms were detected within the hypothalamus of AKR/J and C57BL6/N mice (Fig. 3-4 A, B). Quantification revealed that one DJ-1 isoform in the lower pI range was increased in HF diet-fed AKR/J mice relative to the control group (Fig. 3-4 C) confirming the initial proteome result. In HF diet-fed C57BL/6N mice, the same spot was also increased but lost significance after Bonferroni correction (Fig. 3-4 D).

Fig. 3-3. Total DJ-1 expression in the hypothalamus of male C57BL/6N mice after 10 days of HF or control diet. (A) Validation of the anti-DJ-1 antibody in hypothalamic extracts of *Dj-1*^{-/-} compared to *Dj-1*^{+/+} mice. (B) Representative western blot showing DJ-1 and actin expression. Both target proteins were detected on the same membrane. (C) Densitometric analysis of western blot data. DJ-1 signals were normalized to actin (n = 11). (D) *Dj-1* gene expression measured by quantitative PCR. Transcript levels were normalized to *Hsp90* expression (n = 5). (C, D) Data points represent individual animals.

Fig. 3-4. Comparison of DJ-1 pI isoforms in the hypothalamus of male AKR/J and C57BL/6N mice after 10 days of HF or control diet. (A, B) Hypothalamic extracts were separated in an IEF gel and transferred to a membrane followed by immunodetection of DJ-1. Arrows indicate the DJ-1 isoform found increased in HF diet-fed mice. (C, D) Densitometric quantification of the signal intensities of individual DJ-1 spots ($n = 4$). Student's t-test with Bonferroni correction: * $p < 0.0071$ control vs. HF diet-fed mice. Data generated by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

Because DJ-1 is expressed ubiquitously (Fig. 3-5) [Nagakubo *et al.* 1997; Taira *et al.* 2001; Bonifati *et al.* 2003b; Niki *et al.* 2003; Bader *et al.* 2005; Zhang *et al.* 2005a], we next investigated whether the increase in acidic DJ-1 isoforms can also be observed in other brain areas.

Fig. 3-5. DJ-1 expression in selected mouse tissues. Western blot showing protein homogenates from tissues of a female C57BL/6J mouse (10 μ g protein/lane). hyp – hypothalamus. BAT - brown adipose tissue. psWAT - posterior subcutaneous white adipose tissue. poWAT - periovarial white adipose tissue. M. gastroc - gastrocnemius muscle.

For this, we utilized an automated high-throughput capillary IEF immunoassay (NanoProTM, ProteinSimple) with DJ-1 immunodetection. This method has two major advantages: Up to 96 samples can be processed simultaneously and the use of pI standards allows a precise allocation of pI-values to the individual isoforms. Applying this assay to the hypothalamus, we detected 7 DJ-1 isoforms (Fig. 3-6 A). The distribution of signal intensities differed from the spot pattern obtained with the gel-based IEF-immunoblot method probably due to method-dependent separation characteristics. Thus, the numbering of the individual isoforms does not allow an inter-method comparison.

The pI values of the DJ-1 isoforms detected with the capillary IEF immunoassay ranged from 5.6 to 6.7 (Fig. 3-6 A) in accordance with published data [Natale *et al.* 2010]. The relative peak areas indicated higher abundances of isoform 3 (pI 5.8) and isoform 4 (pI 5.9) within the hypothalamus of HF diet-fed mice (Fig. 3-6 B). Additionally, isoform 6 (pI 6.5) was significantly decreased compared to the control group. We further examined the DJ-1 isoform distribution in brain stem, cerebellum and forebrain. All brain areas showed a similar signal distribution as in the hypothalamus with higher abundances of isoform 3 and 4 in mice fed the HF diet (Fig. 3-6 C-E). Isoform 6 was also significantly decreased by HF diet in the cerebellum and forebrain. In the cerebellum, isoform 7 (pI 6.7) was additionally decreased in the HF diet group.

These results demonstrate a HF diet-induced shift in the composition of the DJ-1 protein pool with accumulation of more acidic isoforms throughout the brain.

Fig. 3-6. Comparison of DJ-1 pI isoforms in selected brain areas of C57BL/6N mice maintained on a HF or control diet for 10 days. Protein extracts were analyzed using an automated capillary IEF immunoassay (NanoPro™ 1000, ProteinSimple). **(A)** Electropherogram exemplifying the pI distribution of DJ-1 isoforms in the hypothalamus and brain as detected via chemifluorescence. Each peak likely corresponds to one DJ-1 isoform. The hypothalamic extract of a *Dj-1* deficient mouse (Hyp *Dj-1*^{-/-}) served as negative control. **(B-E)** Quantification of peak areas. Forebrain excludes the hypothalamus. Student's t-test with Bonferroni correction: *p < 0.0071, **p < 0.0014, ***p < 0.0001 control vs. HF diet-fed mice. $n_{\text{hypothalamus}} = 5$, $n_{\text{brain stem}} = 6$, $n_{\text{cerebellum}} = 6$, $n_{\text{forebrain}} = 5-6$. Data generated by Dr. Daniela Besong Agbo and Dr. Hans Klafki, LVR-Klinikum Essen, Germany.

3.2.2 High-fat diet-induced accumulation of acidic DJ-1 isoforms in peripheral tissues

We furthermore applied the capillary IEF immunoassay to selected peripheral tissues. As in the brain, seven isoforms were detected with matching pls. In gastrocnemius muscle and pancreas, DJ-1 isoforms 1 (pl 5.6), 2 (pl 5.7), 3 (pl 5.8) and 4 (pl 5.9) were increased in the HF diet-fed animals, while isoform 6 (pl 6.5) was decreased (Fig. 3-7 A, B). Gastrocnemius muscle showed an additional HF diet-induced decrease in isoform 7 (pl 6.7). In liver, only isoform 2 (pl 5.7) was significantly increased upon HF-feeding (Fig. 3-7 C). In contrast, a HF diet-induced shift of DJ-1 isoforms was absent in epididymal white adipose tissue (eWAT, Fig. 3-7 D). The result for eWAT was confirmed using the gel-based IEF method with subsequent membrane transfer and DJ-1 immunodetection (Supplementary Fig. S1).

These results clearly show tissue specific differences in the distribution of DJ-1 isoforms as well as in the susceptibility towards HF diet-induced changes of the DJ-1 protein pool composition.

Fig. 3-7. Comparison of DJ-1 pI isoforms in peripheral tissues of C57BL/6N mice maintained on a HF or control diet for 10 days. Protein extracts were analyzed using an automated capillary IEF immunoassay (NanoPro™ 1000, ProteinSimple). Shown is the quantification of peak areas of electropherograms (see Supplementary Fig. S2). Student's t-test with Bonferroni correction: * $p < 0.0071$, ** $p < 0.0014$, *** $p < 0.0001$ control vs. HF diet-fed mice. $n_{gastrocnemius\ muscle} = 5-6$, $n_{pancreas} = 5$, $n_{liver} = 6$, $n_{epididymal\ WAT} = 3$ (median \pm range). Data was generated by Dr. Daniela Besong Agbo and Dr. Hans Klafki, LVR-Klinikum Essen, Germany.

3.2.3 The high-fat diet-induced shift of DJ-1 isoforms is influenced by the length of feeding

The HF diet-induced increase of acidic DJ-1 isoforms in the hypothalamus observed after 10 days of feeding raised the question whether this effect can be detected at earlier timepoints and if the shift is stable when the feeding period is prolonged. We therefore examined the hypothalami of mice that were fed a HF or control diet for two days or three months. Two days of HF diet did not result in a significant increase in body mass or fat mass. However, body mass and fat mass of control diet-fed mice was slightly reduced resulting in a significant difference in body and fat mass gain between HF and control diet-fed mice after two days (Supplementary Table S1). Lean mass was unaffected by the diets. After three months of feeding, body mass, fat and lean mass were clearly elevated in HF diet-fed mice compared to controls (Supplementary Table S1).

Fig. 3-8. Comparison of DJ-1 pI isoforms in the hypothalamus of C57BL/6N mice maintained on a HF or control diet for 2 days (A, C) or 3 months (B, D). Protein extracts were analyzed using an automated capillary IEF immunoassay (NanoPro™ 1000, ProteinSimple). (A, B) Electropherograms exemplifying the pI distribution of DJ-1 isoforms. (C, D) Quantification of peak areas (n = 5). Student's t-test with Bonferroni correction: *p < 0.0071, ***p < 0.0001 control vs. HF diet-fed mice. Data generated by Dr. Daniela Besong Agbo and Dr. Hans Klafki, LVR-Klinikum Essen, Germany.

Using the capillary IEF immunoassay, the detected DJ-1 isoforms were analogous to the hypothalamic samples after 10 days of feeding although the peaks in this sample set showed a slightly different pattern, with the peak of isoform 6 (pI 6.5) having a similar height as the peak for isoform 5 (pI 6.2) (compare Fig. 3-8 A, B and Fig. 3-6 A). However, due to high inter-assay coefficients of variation different runs cannot reliably be compared quantitatively [Besong Agbo et al. 2013].

After two days, HF and control diet-fed mice showed comparable relative peak areas for all DJ-1 isoforms (Fig. 3-8 C). In contrast, after three months of feeding a significant difference between HF and control diet-fed animals for isoform 3 (pI 5.7) and isoform 4 (pI 5.9) was detected (Fig. 3-8 D). These results indicate that the shift of DJ-1 isoforms is not an acute effect but remains at least partly stable once established.

3.2.4 N-acetylcysteine increases glutathione levels but does not affect the abundances of DJ-1 isoforms in the brain

DJ-1 isoforms with a low pI are increased in cultured cells exposed to oxidative stresses [Mitsumoto & Nakagawa 2001; Bandopadhyay et al. 2004; Canet-Aviles et al. 2004; Kinumi et al. 2004; Taira et al. 2004; Zhou & Freed 2005; Choi et al. 2006; Kim et al. 2009b; Natale et al. 2010]. Furthermore, DJ-1 regulates glutathione levels through regulation of glutamate cysteine ligase, the rate limiting enzyme in glutathione synthesis [Zhou & Freed 2005; Liu et al. 2008; Zhong & Xu 2008] and many functions of DJ-1 are influenced by changes in the cellular redox state (see Fig. 1-5). Thus, we began to investigate whether the HF diet-induced increase of acidic DJ-1 isoforms can be reversed. Mice were treated with N-acetylcysteine (NAC) that is known to increase glutathione levels which in turn affect the cellular redox balance [Fujii et al. 2011; Wilson 2011]. NAC was supplied in the drinking water during the 10 days the mice received a HF or control diet. Mice showed no aversion to the NAC water as they consumed on average 4.5 g of water per day which is similar to what we observed in experiments without NAC supplementation. The cumulative water consumption for the 10-day-period did not differ between HF and control diet-fed mice (47.5 ± 5.1 g for control vs. 42.4 ± 8.0 g for HF diet-fed mice, Student's t-test $p = 0.149$). HF diet-induced gain of body mass and fat mass was comparable to other cohorts fed for 10 days without NAC treatment (Supplementary Table S1). The effect of NAC treatment on reduced (GSH) and oxidized glutathione (GSSG) was measured in brain tissue and gastrocnemius muscle. HF feeding increased reduced glutathione levels in skeletal muscle leading to a higher GSH to GSSG ratio while in the brain, glutathione levels were comparable between HF and control mice (Fig. 3-9). NAC treatment significantly elevated both GSH and GSSG levels in brain and gastrocnemius muscle resulting in a significantly reduced ratio of GSH to GSSG which was

more pronounced in muscle compared to brain tissue (Fig. 3-9 C, F). Glutathione levels were raised to a similar level in HF and control diet-fed mice.

Fig. 3-9. Effect of N-acetylcysteine (NAC) on glutathione levels in brain and gastrocnemius muscle of C57BL/6N mice after 10 days of HF or control diet. NAC (1%) was supplied in the drinking water during the 10-day feeding period. Reduced (GSH) and oxidized glutathione (GSSG) were measured utilizing an enzymatic recycling method. ANOVA: significant effect of treatment on GSH and GSSG levels ($p < 0.0001$) as well as on GSH/GSSG ratios ($p < 0.05$) for both brain and muscle; effect of diet: significant for muscle GSH and GSH/GSSG ratio ($p < 0.5$); diet-treatment interaction: not significant. Bonferroni posttest: # $p < 0.05$, ### $p < 0.001$ basal vs. NAC treated; ** $p < 0.01$ HF vs. control diet-fed mice. Statistics were performed on log-transformed data. $n = 8$.

Lysates prepared from hypothalami were separated by gel-based IEF with subsequent membrane transfer and DJ-1 immunodetection. The pattern of individual DJ-1 pI isoforms was comparable to the one obtained without NAC treatment (compare Fig. 3-10 A with Fig. 3-4 C). Furthermore, the same increase in the abundance of isoform 4 was detected in HF mice (compare Fig. 3-10 B with Fig. 3-4 D) although this was not significant after Bonferroni correction. This result suggests that NAC has no influence on the formation of lower pI isoforms of DJ-1 in the hypothalamus.

Fig. 3-10. Comparison of DJ-1 pI isoforms in the hypothalamus of male C57BL/6N mice treated with N-acetylcysteine (NAC) during 10 days of HF or control diet. NAC (1%) was supplied in the drinking water. **(A)** Hypothalamic extracts were separated via IEF. Gels were transferred to a membrane followed by immunodetection of DJ-1. Arrows indicate the DJ-1 isoform found increased in HF mice. **(B)** Densitometric quantification of the signal intensities of individual DJ-1 spots (n = 4). Student's t-test: no significances after Bonferroni correction. Data generated by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

3.2.5 Influence of high-fat feeding on the mitochondrial localization of DJ-1 in the brain

DJ-1 is predominantly a cytosolic protein but increases its localization to mitochondria in response to oxidative stress as observed in human neuroblastoma cells as well as mouse brain [Nagakubo et al. 1997; Canet-Aviles et al. 2004; Taira et al. 2004; Blackinton et al. 2005; Zhang et al. 2005a; Lev et al. 2008; Blackinton et al. 2009; Zhong et al. 2009]. To investigate whether the localization of DJ-1 to mitochondria in the brain is affected by HF diet-feeding, mitochondrial and cytosolic fractions of brain tissue from C57BL6/N mice maintained on HF or control diet for 10 days were prepared. Crude mitochondrial fractions were treated with a sodium

carbonate buffer to detach loosely associated proteins, yielding the 'mitochondrial supernatant (mito SN)' as a third fraction (Fig. 2-3). Using conventional western blot analysis targeting total DJ-1, we detected about half of the DJ-1 pool localized in the cytosol, one fifth in the mitochondrial fraction and one third in the mito SN without differences between HF or control diet-fed mice (Fig. 3-11 A, B). Calculating the ratio of mitochondrial to cytosolic DJ-1 revealed a tendency towards decreased DJ-1 translocation to mitochondria upon HF diet-feeding (Fig. 3-11 C) which did not reach significance (Student's t-test $p = 0.1825$).

Fig. 3-11. DJ-1 expression of cytosolic and mitochondrial fractions obtained from brain tissue of C57BL/6N mice maintained on a HF or control diet for 10 days. (A) Example western blot of separated cytosolic and mitochondrial fractions as well as mitochondrial supernatant (mito SN, see Chapter 2.8 for explanation). Target proteins were immunodetected on the same membrane. The inner mitochondrial membrane protein Cytochrome c oxidase subunit 4 (COXIV) was used as quality control for fractionation efficiency. (B) Densitometric analysis quantifying the relative distribution of DJ-1 between the fractions. (C) Ratio of mitochondrial to cytosolic DJ-1 content. $n = 7$. Mito – mitochondria.

Next, we examined the distribution of individual DJ-1 isoforms between these cell compartments by subjecting mitochondrial and cytosolic fractions to the capillary IEF immunoassay. The peak distribution in mitochondria as well as in the cytosol differed from the isoform pattern observed in whole tissue extracts with mitochondria containing one dominant isoform (pI 6.2) (compare Fig. 3-12 A, B with Fig. 3-6 A). No differences were detected for any DJ-1 isoform between HF and control diet-fed mice (Fig. 3-12 C, D), although peak quantification was difficult in mitochondrial fractions due to lower DJ-1

abundance and thus higher signal-to-noise ratios. However, summing up the individual peak areas showed a tendency towards decreased DJ-1 content in mitochondria of HF mice as compared to controls (Fig. 3-12 E). This was significant when expressed as the ratio of mitochondrial to cytosolic DJ-1 (Fig. 3-12 F) confirming the trend seen in the western blot analysis. This suggests that the translocation of DJ-1 from the cytosol to mitochondria in brain tissue is attenuated by HF feeding.

Fig. 3-12. Comparison of DJ-1 pI isoforms in the cytosolic and mitochondrial fraction obtained from brain tissue of C57BL/6N mice maintained on a HF or control diet for 10 days. Protein extracts were analyzed using an automated capillary IEF immunoassay (NanoPro™, ProteinSimple). (A, B) Electropherograms exemplifying the pI distribution of DJ-1 isoforms. (C, D) Quantification of individual peak areas. (E) Total peak area as the sum of individual peak areas. ANOVA: effect for fraction: $p < 0.0001$; effect for diet: not significant; Bonferroni posttest: ### $p < 0.001$ cytosol vs. mitochondria. (F) Ratio of mitochondrial to cytosolic total peak area. Student's t-test: * $p < 0.05$. $n_{\text{cytosol}} = 4$, $n_{\text{mitochondria}} = 5$. Mito – mitochondria. AU – arbitrary units. Data generated by Dr. Daniela Besong Agbo and Dr. Hans Klafki, LVR-Klinikum Essen, Germany.

3.3 Brain mitochondrial function and ROS production are normal after 10 days of high-fat diet

DJ-1 plays a role in the integrity of mitochondria by contributing to the maintenance of a stable environment inside this organelle [Zhang *et al.* 2005a; Zhong & Xu 2008; Krebiehl *et al.* 2010]. Loss of *Dj-1* results in abnormal mitochondrial morphology, reduced mitochondrial respiration and membrane potential as well as elevated ROS levels (see Chapter 1-4) [Andres-Mateos *et al.* 2007; Irrcher *et al.* 2010; Krebiehl *et al.* 2010]. Apart from DJ-1, three further candidates from the initial proteome study investigating the influence of a 10-day HF diet on hypothalamic protein expression localize to mitochondria: Isoform 1 of NADH dehydrogenase flavoprotein 2 (upregulated by HF diet in SWR/J mice), prohibitin (upregulated by HF diet in C57BL/6N mice) and Acyl-coenzyme A thioesterase 13 (downregulated by HF diet in AKR/J mice). Moreover, alpha-synuclein (downregulated by HF diet in C57BL/6N mice), of which gene mutations are also associated with inherited forms of PD, can interact with mitochondria and its overexpression is discussed to impair mitochondrial function [Nakamura *et al.* 2008].

Thus, we characterized the mitochondrial function after 10 days of HF or control diet in isolated brain mitochondria from 7-week-old male C57BL/6N mice. First, the assembly of respiratory chain complexes was examined. For each of the five complexes, the expression levels of one subunit known to be labile in the unassembled state of its complex was determined via western blot. Densitometric analysis showed that the assembly of respiratory chain complexes in the brains of HF mice is comparable to controls (Fig. 3-13).

Fig. 3-13. Relative protein levels of respiratory chain complex subunits involved in complex assembly.

One representative subunit of each of the five respiratory chain complexes was detected using a mixture of antibodies (OXPHOS, MitoScience). These subunits are labile when the respective complex is not assembled. (A) Western blot showing isolated brain mitochondria from C57BL/6N mice after 10 days of HF or control diet. (B) Densitometric analysis. Data was normalized to the mean of the control diet group for each complex. Values are means \pm SD ($n = 4$). CI subunit: NDUFB8 ~ 20 kDa, CII subunit: 30 kDa ~ 30 kDa, CIII subunit: Core 2 ~ 47 kDa, CIV subunit I ~ 39 kDa, CV subunit: alpha ~ 53 kDa.

Second, respiration was measured in a Clark electrode. Succinate or a combination of glutamate and malate were used as substrates to measure complex II or complex I respiration, respectively. After the addition of substrate, ADP was added to measure state 3 (phosphorylating) respiration followed by oligomycin, an inhibitor of the ATP synthase, to measure state 4 (non-phosphorylating) respiration. Finally, adding the uncoupler FCCP allowed the determination of the maximal oxygen consumption rate. Mitochondria from HF or control diet-fed mice showed similar rates for complex I and II-dependent respiration under all conditions measured (Fig. 3-14 A, C) as well as similar respiratory control ratios (RCR) (Fig. 3-14 B, D).

Fig. 3-14. Respiration of isolated brain mitochondria from C57BL/6N mice after 10 days of HF or control diet. (A, C) Oxygen consumption rate was measured with a Clark electrode in the presence of 5 mM glutamate + 5 mM malate (A) or 5 mM succinate (C). The addition of substrate was followed by 1 mM ADP, 2 mg/l oligomycin and 2.5 μ M FCCP. Succinate-dependent respiration was measured in the presence of 8 μ M rotenone. (B, D) Respiratory control ratios (RCR) under glutamate/malate (B) and succinate (D) respiration. The RCR represents the increase of phosphorylating respiration (+ ADP) over respiration in the presence of excess substrate. Data includes the results of 2-3 independent experiments. n = 16 (A, B); n = 10-11 (C, D).

Third, the mitochondrial membrane potential $\Delta\Psi_m$ was estimated using the fluorescence cationic dye Safranin O that accumulates inside energized mitochondria where its fluorescence is quenched [Akerman & Wikstrom 1976]. Isolated brain mitochondria from HF or control diet-fed mice equally increased their membrane potential as indicated by decreased

fluorescence after the addition of the substrates succinate or glutamate/malate (Fig. 3-15 B, E). Moreover, when uncoupled with FCCP, mitochondria from HF or control diet-fed animals decreased their $\Delta\Psi_m$ to the same extent (Fig. 3-15 C, F).

Fig. 3-15. Membrane potential $\Delta\Psi_m$ detected by Safranin O fluorescence in isolated brain mitochondria of C57BL6/N mice after 10 days of HF or control diet. (A, D) Course of Safranin O fluorescence over time. As substrates 5 mM glutamate + 5 mM malate (A-C) or 5 mM succinate (C-E) were injected after 30 minutes followed by 0.3 μM FCCP 30 minutes later. DMSO was added as solvent control for FCCP. The last data point before the addition of substrate was set to 100 %. Values are means \pm SD (n = 6). (B, E) Maximal decrease of Safranin O fluorescence after the addition of glutamate/malate (B) or succinate (D). (C, F) Increase of Safranin O fluorescence after the addition of FCCP.

Fourth, the hydrogen peroxide production was assayed with the fluorescent dye Amplex[®] Red in brain mitochondria respiring on succinate or glutamate/malate. H_2O_2 production rates were determined at basal levels, after the inhibition of complex I with rotenone, after the inhibition of complex III with antimycin as well as under phosphorylating conditions (+ ADP) or after several combinations of the above. Under all conditions measured, H_2O_2 production was comparable between HF or control diet-fed mice (Fig. 3-16).

Fig. 3-16. H₂O₂ production in isolated brain mitochondria of C57BL6/N mice after 10 days of HF or control diet. The generation of H₂O₂ was detected with the fluorescent dye Amplex[®] Red in mitochondria respiring on 5 mM glutamate + 5 mM malate (**A**) or 5 mM succinate (**B**). In separate preparations, 2 μ M rotenone, 50 μ M antimycin A or 1 mM ADP were added. N-numbers are indicated for each condition.

Last, the expression levels of the mitochondrial antioxidant enzyme manganese superoxide dismutase (SOD2) that converts superoxide anion radicals to H₂O₂ and oxygen were unchanged upon HF feeding (Fig. 3-17).

Fig. 3-17. SOD2 expression in isolated brain mitochondria of male C57BL/6N mice after 10 days of HF or control diet feeding. (**A**) Western blot of mitochondrial fraction targeting manganese superoxide dismutase (SOD2) and voltage-dependent anion channel (VDAC). Both targets were immunodetected on the same membrane. (**B**) Densitometric analysis of western blot data. SOD2 signals were normalized to VDAC (n = 5-6).

Conclusively, the function of brain mitochondria in terms of respiratory chain complex assembly, respiration, membrane potential, H₂O₂ production and SOD2 content is not influenced by a short-term HF diet-intervention and the associated changes of the intracellular DJ-1 pool composition.

3.4 Phenotypic characterization of high-fat diet challenged *Dj-1*^{-/-} mice

DJ-1 emerged as a candidate protein from the initial proteome analysis investigating acute alterations in the hypothalamus in response to a short-term diet intervention (Chapter 3.1). We therefore investigated the susceptibility of *Dj-1* deficient mice (*Dj-1*^{-/-}) to DIO.

3.4.1 Higher fat accumulation in *Dj-1*^{-/-} mice after 14 weeks of high-fat feeding

Male and female *Dj-1*^{-/-} mice and their wildtype littermates were fed a HF or control diet for 14 weeks. Body mass and body composition were recorded every two weeks (Fig. 3-18). At the age of 4 weeks when the feeding was started, there were no differences in body mass, fat or lean mass between the genotypes in male mice. In contrast, female *Dj-1*^{-/-} mice had a reduced lean mass at this age (Supplementary Table S3). The level of DIO was lower in female compared to male mice (Fig. 3-18 B and E) but HF diet-feeding resulted in a significant gain in body mass, fat and lean mass within 14 weeks in both sexes (Table 3-2). No significant genotype differences within the diet groups were observed for either of these parameters after 14 weeks of feeding (Table 3-2). Correlating fat or lean mass with body mass nevertheless suggested an increased HF diet-induced body fat accumulation in *Dj-1*^{-/-} mice compared to wildtype mice with a corresponding decrease in lean mass (Fig. 3-19).

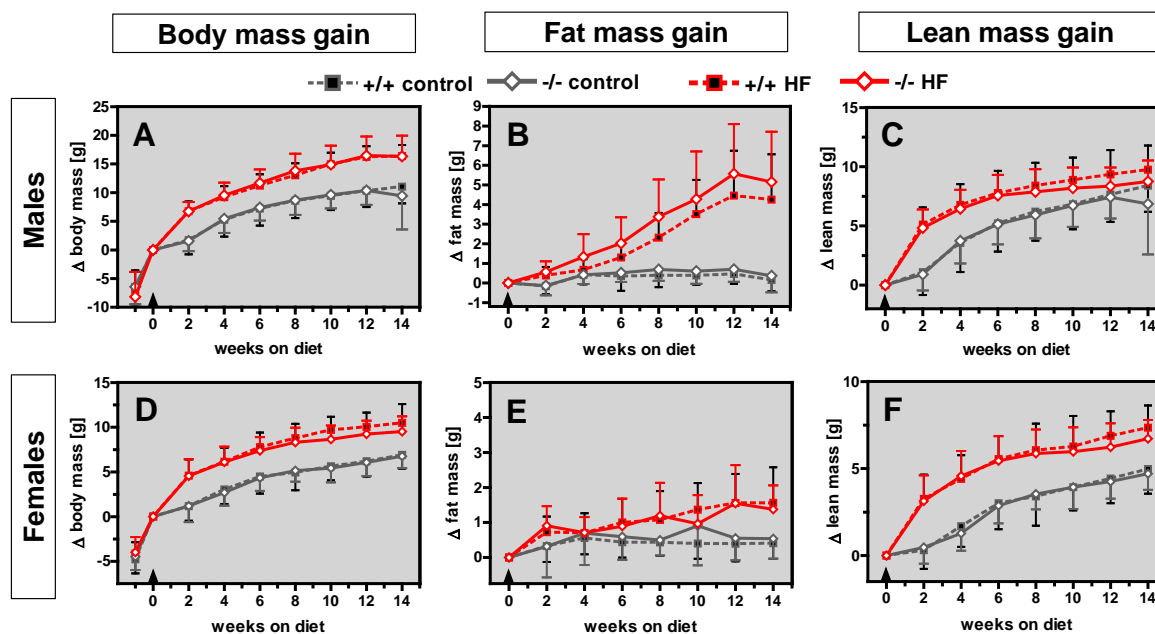

Fig. 3-18. Gain of body mass, fat and lean mass in male (top) and female (bottom) *Dj-1*^{-/-} and *Dj-1*^{+/+} mice maintained on HF or control diet for 14 weeks. Arrows indicate the diet change at the age of 4 weeks. Values are means \pm SD ($n_{males} = 14-20$; $n_{females} = 13-16$).

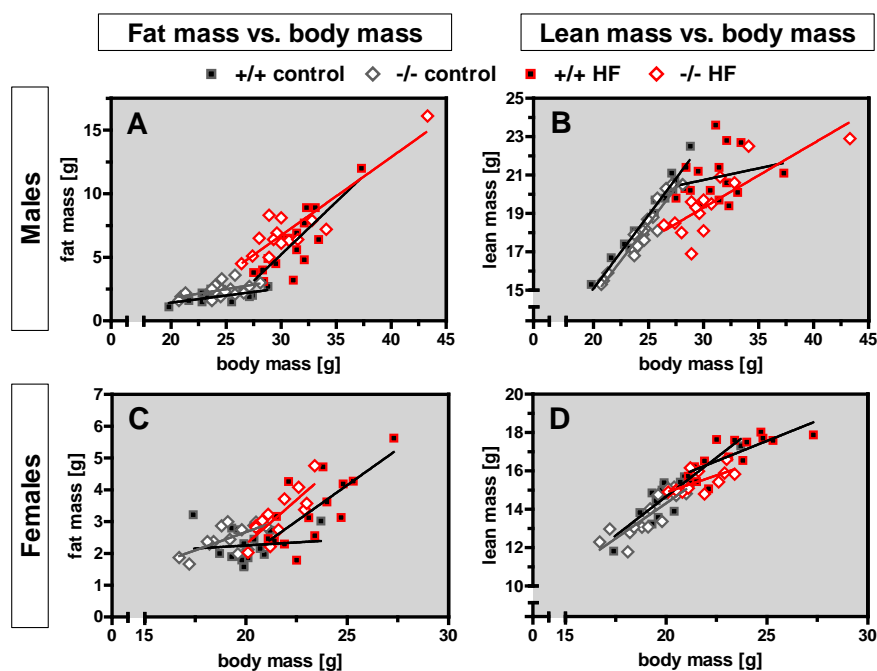

Fig. 3-19. Fat and lean mass related to body mass in male (top) and female (bottom) $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice after 14 weeks of HF or control diet.

Hence, we performed an analysis of covariance (ANCOVA) to adjust fat and lean mass, respectively, to the body mass as a covariate. The adjusted fat mass was significantly increased while lean mass was significantly decreased in $Dj-1^{-/-}$ mice compared to $Dj-1^{+/+}$ mice of both sexes (Table 3-2). These effects were more pronounced under HF diet compared to control diet.

In male mice, additionally, two fat pads (epididymal, eWAT, and posterior subcutaneous white adipose tissue, psWAT) were weighed at the end of the feeding period. The absolute fat pad masses were significantly increased in HF diet-fed mice without a significant genotype difference (Table 3-3). When adjusted for body mass, the visceral eWAT was increased in HF diet-fed $Dj-1^{-/-}$ mice compared to wildtype mice on the same diet, while the increase in psWAT failed to reach significance (Fig. 3-20; Table 3-3). Taken together, these results demonstrate an altered partitioning of body energy resources in $Dj-1^{-/-}$ mice when fed a HF diet for 14 weeks characterized by higher storage of fat at the expense of lean mass.

Table 3-2. Gain of body mass, fat and lean mass in male (top) and female (bottom) *Dj-1^{-/-}* and *Dj-1^{+/+}* mice after 14 weeks of HF or control diet. §Adjusted fat and lean mass result from ANCOVA analysis with adjustment to the mean body mass of the respective diet group.

3.4.2 Prolonged HF feeding does not aggravate fat storage in *Dj-1^{-/-}* mice

To investigate whether the mild increase in fat storage in HF diet-fed *Dj-1^{-/-}* mice increases with age, we extended the feeding period for part of the mice to 32 weeks (Fig. 3-21). Female mice fed a HF diet showed a drastic increase of body and fat mass from the 16th week on (Fig. 3-21 E). Within 32 weeks of feeding, both male and female mice gained significantly more body mass and fat mass on HF diet compared to control diet-fed mice, while the lean mass was unaffected (Table 3-4). The higher HF diet-induced fat accumulation in *Dj-1^{-/-}* mice was abrogated after 32 weeks of feeding in male mice (Fig. 3-22 A, B; Table 3-4). In female mice, body mass-adjusted fat mass was significantly increased in control diet-fed *Dj-1^{-/-}* mice (Table 3-4) while lean mass was reduced in *Dj-1^{-/-}* mice compared to wildtype mice regardless of diet (Fig. 3-22 C, D; Table 3-4).

	HF	18.2 ± 0.7	17.3 ± 0.7*			

Values are mean ± SD ($n_{\text{males}} = 5-8$, $n_{\text{females}} = 4-7$). Bonferroni post-test: * $p < 0.05$ *Dj-1^{-/-}* vs. *Dj-1^{+/+}* mice.

Weights of dissected fat pads revealed a HF diet-induced increase in subcutaneous WAT in female *Dj-1^{-/-}* mice after adjustment for body mass, while the visceral periovarial WAT (poWAT) was comparable to wildtype mice (Fig. 3-23 D, E; Table 3-5). No genotype differences were detected for fat pad weights in male mice (Fig. 3-23 A, B; Table 3-5). The gastrocnemius muscle wet weight was significantly decreased in male and female *Dj-1^{-/-}* mice compared to wildtype mice regardless of diet (Fig 3-23 C, F; Table 3-5).

Thus, the prolonged exposure to HF diet ameliorates the increased adiposity in male *Dj-1^{-/-}* mice. The HF diet-induced changes in body composition are delayed in female animals. After 32 weeks of feeding, female *Dj-1^{-/-}* mice have higher total fat mass under control diet conditions, but the subcutaneous WAT is increased by HF diet compared to wildtype mice. Moreover, *Dj-1^{-/-}* mice show an age-dependent decrease in lean mass that is

independent of diet. Conclusively, the altered body composition in *Dj-1^{-/-}* mice is a transient effect depending on the duration of HF diet-feeding and/or age.

Table 3-5: Weights of dissected fat pads and muscle of male (top) and female (bottom) *Dj-1^{-/-}* and *Dj-1^{+/+}* mice after 32 weeks of HF or control diet. [§]Adjusted fat pad weights result from ANCOVA analysis with adjustment to the mean body mass of the respective diet group.

3.4.3 $Dj-1^{-/-}$ mice are hypoactive without detectable changes in energy intake and energy expenditure

To find possible causes underlying the altered body composition after 14 weeks of HF diet, we monitored the energy intake and spontaneous locomotor activity of male mice over 2-3 days. Towards the end of the 14-week feeding period, the energy intake over 24 hours or during the dark phase did not differ between HF or control diet-fed mice or between the genotypes (Table 3-6).

$Dj-1^{-/-}$ mice displayed significantly less rearing activity, travelled a smaller distance and were slower compared to $Dj-1^{+/+}$ mice (Table 3-6). A trend in the same direction was detected for total activity as the sum of all beam break counts. This genotype effect is more pronounced in control diet-fed animals because wildtype mice fed a HF diet tend to move less compared to their control diet-fed counterparts, bringing their activity level down to the level of $Dj-1^{-/-}$ mice. When total counts were assigned to ambulatory or fine activity, it became apparent that the lower activity level resulted from reduced ambulatory movement of $Dj-1^{-/-}$ mice, since fine movement was unaltered between the genotypes (Table 3-6). Thus, $Dj-1^{-/-}$ mice were hypoactive independent of diet but this was not reflected in altered energy intake.

Table 3-6. Energy intake (EI) and spontaneous locomotor activity of male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on a HF or control diet for 14 weeks. Animals were kept in the feeding-drinking-activity system (TSE Systems) for 2-3 days. EI is expressed per 24 hours or per dark-phase. Activity parameters are the mean of 2-3 consecutive dark-phases. Animals with a CV exceeding 33 % (for EI) or exceeding 40 % (for activity) were excluded. Total activity refers to beam break counts in X, Y and Z direction, horizontal activity to X and Y direction and rearing activity to Z direction (vertical movement).

We further performed indirect calorimetry measurements towards the end of the 14-week feeding period in male mice. The oxygen consumption ($\dot{V}O_2$) measured over 3 days at 22°C and the resulting mean metabolic rate expressed as heat production ($HP_{22^\circ C, ad-lib}$) tended to be higher in HF compared to control diet-fed mice but was comparable between *Dj-1^{-/-}* and *Dj-1^{+/+}* mice within each diet group (Fig. 3-24; Table 3-7). Metabolic rate depends on body mass as well as body composition since lean mass and adipose tissue are not equally metabolically active. The specific metabolic activity of adipose tissue in mice is estimated to be 15-25 % of the metabolic activity of lean mass [Arch et al. 2006]. We normalized the energy expenditure data to the sum of lean mass + 0.2 * fat mass [g], as suggested by Even & Nadkarni [2012] because this method eliminated the body mass dependency (Fig. 3-25).

Normalization to body composition abolished the trend of increased $HP_{22^{\circ}C, ad-lib}$ in HF diet-fed mice (Table 3-7).

Fig. 3-24. Oxygen consumption ($\dot{V}O_2$) of male $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice maintained on control (A) or HF (B) diet for 14 weeks. Indirect calorimetry was performed at $22^{\circ}C$. Shaded areas indicate dark phases. Values are means \pm SD (n = 6).

Table 3-7. Respiratory exchange ratio (RER) and heat production (HP) of male $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice maintained on a HF or control diet for 14 weeks measured by indirect calorimetry. For RER and $HP_{22^{\circ}C, ad-lib}$, the mean of two measuring days per animal was taken. $HP_{30^{\circ}C, pa}$ was measured at thermoneutrality after animals were deprived of food for 6 hours.

Values are means \pm SD (n = 6). *Ad lib* – *ad libitum*. Pa – postabsorptive. LM – lean mass. FM – fat mass. [#]Ratio of $HP_{22^{\circ}C, ad-lib}$ to $HP_{30^{\circ}C, pa}$ was calculated using the values adjusted for body composition.

Fig. 3-25. Effect of adjustment method on body mass dependency of heat production (HP). Indirect calorimetry was performed at 22°C with *ad libitum* access to food. Subgroups include male or female *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on a HF or control diet for 14 or 32 weeks. Each data point represents an individual animal. (A) HP positively correlates with body mass (Pearson product-moment correlation, males 14 weeks: $r = 0.55$, $p = 0.0054$; 32 weeks males: $r = 0.7$, $p < 0.0001$; 32 weeks females: $r = 0.90$, $p < 0.0001$). (B) HP normalized to g body mass negatively correlates with body mass (Pearson product-moment correlation, 14 weeks males: $r = -0.46$, $p = 0.0237$; 32 weeks males: $r = -0.81$, $p < 0.0001$; 32 weeks females: $r = -0.90$, $p < 0.0001$). (C) Normalization to lean mass (LM) + 0.2 * fat mass (FM) eliminates the dependency of HP from body mass (Pearson product-moment correlation, 14 weeks males: $r = 0.15$, not significant; 32 weeks males: $r = -0.04$, not significant; 32 weeks females: $r = 0.30$, not significant). Body composition was measured via NMR spectrometry shortly before performing indirect calorimetry.

To measure the basal metabolic rate (BMR), animals were deprived of food for 6 hours during the day while temperature was increased to 30°C. The resultant HP of this postabsorptive (pa) and thermoneutral state ($HP_{30^{\circ}C,pa}$) was significantly increased in HF diet-fed mice compared to wildtype mice but the diet dependency was abolished after normalization to body composition (Table 3-7). BMR was not significantly different between the genotypes, but a trend towards higher $HP_{30^{\circ}C,pa}$ in *Dj-1^{-/-}* mice was detected after normalization to body composition. The increase of $HP_{22^{\circ}C,ad-lib}$ over basal conditions ($HP_{22^{\circ}C,ad-lib}/HP_{30^{\circ}C,pa}$) calculated from the body composition-adjusted values was comparable between *Dj-1^{-/-}* and *Dj-1^{+/+}* mice on both diets (Table 3-7). Thus, the changes in body composition of *Dj-1^{-/-}* mice are not attributed to measurable changes in the metabolic rate.

After 32 weeks of feeding, the oxygen consumption of HF diet-fed mice was clearly increased compared to controls (Fig. 3-26) and the resultant $HP_{22^{\circ}C,ad-lib}$ and $HP_{30^{\circ}C,pa}$ were significantly higher in HF diet-fed animals but similar between $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice (Table 3-8). When related to body composition, the diet effect of $HP_{22^{\circ}C,ad-lib}$ was abolished in male mice but persisted in HF diet-fed female mice. Moreover, the diet effect persisted for HP under basal conditions ($HP_{30^{\circ}C,pa}$) in male and female mice (Table 3-8). Similar to the trend observed in male mice after 14 weeks of HF diet-feeding, the body composition-corrected BMR was significantly higher in female $Dj-1^{-/-}$ mice compared to wildtype mice with a corresponding lower increase of $HP_{22^{\circ}C,ad-lib}$ over basal conditions (Table 3-8). Thus, $HP_{30^{\circ}C,pa}$ was increased in those HF diet-fed $Dj-1^{-/-}$ mice that showed a higher adiposity compared to wildtype mice.

Fig. 3-26. Oxygen consumption ($\dot{V}O_2$) of male (top) and female (bottom) $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice maintained on control (A, C) or HF diet (B, D) for 32 weeks. Indirect calorimetry was performed at 22°C. Shaded areas indicate dark-phases. Values are means \pm SD ($n_{males} = 5-8$; $n_{females} = 4-7$).

3.4.4 *Dj-1* deficiency influences glucose levels without affecting glucose tolerance

Since DIO negatively affects glucose metabolism, we tested whether the extent of this impairment varies between *Dj-1^{-/-}* and *Dj-1^{+/+}* mice. First, plasma glucose and insulin levels were measured in male *ad libitum* fed mice. Plasma glucose levels were not different between wildtype mice fed a HF or control diet for 14 weeks but were increased by HF diet in *Dj-1^{-/-}* mice, resulting in a significant diet effect which is dependent on genotype (Table 3-9). Plasma insulin levels were increased about twofold by HF diet as well as in mice lacking *Dj-1* in comparison to wildtype control diet-fed mice. Due to high intra-group variability this interaction failed to reach significance. Insulin sensitivity was estimated from glucose and insulin levels applying the homeostatic model assessment of insulin resistance (HOMA-IR) [Hoeks *et al.* 2011]. As for insulin levels, HOMA-IR indices tended to be doubled after 14 weeks of HF diet in wildtype mice as well as in *Dj-1* deficient mice compared to wildtype control-diet fed mice (Table 3-9). These results indicate that *Dj-1^{-/-}* mice are initially less insulin sensitive compared to wildtype mice. Wildtype mice reach this lower level of insulin sensitivity after 14 weeks of HF diet-feeding, while insulin sensitivity is not further aggravated by HF diet in *Dj-1^{-/-}* mice.

Table 3-9. Plasma glucose and insulin levels of male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice fed *ad libitum* with a HF or control diet for 14 (top) or 32 weeks (bottom). HOMA-IR = (insulin [$\mu\text{U}\cdot\text{mL}^{-1}$]*glucose [$\text{mmol}\cdot\text{l}^{-1}$])*22.5⁻¹.

	HF	59.6 ± 49.3	39.9 ± 14.0			

Values are means ± SD ($n_{14\text{ weeks}} = 9-11$; $n_{32\text{ weeks}} = 4-8$). *Statistic was performed with log-transformed data.

After 32 weeks of HF diet-feeding, plasma insulin levels and HOMA-IR indices were significantly increased in both genotypes indicating HF diet-induced insulin resistance (Table 3-9). The differences between control diet-fed *Dj-1^{-/-}* and *Dj-1^{+/+}* mice were less pronounced compared to 14 weeks of HF diet-feeding. This reflects the transient phenotype that was observed for body composition.

Second, we performed i.p. glucose tolerance tests (i.p. GTT) towards the end of the feeding periods in male and female mice. Glucose clearance was comparable between control diet-fed *Dj-1^{-/-}* and *Dj-1^{+/+}* mice (Fig. 3-27). In both sexes, HF diet-feeding for 14 or 32 weeks impaired the glucose tolerance of *Dj-1^{-/-}* and *Dj-1^{+/+}* mice to the same extent (Fig. 3-27).

Fig. 3-27. Intraperitoneal glucose tolerance test (i.p. GTT) of male and female *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on a HF or control diet for 14 or 32 weeks. After animals were deprived of food for 6 hours, they received an i.p. injection of 2 g glucose*kg⁻¹ body mass. Glucose was monitored in tail blood 15, 30, 60 and 120 min after glucose administration. Values are means \pm SD ($n_{\text{males};14\text{weeks}} = 8-12$; $n_{\text{females};14\text{weeks}} = 7-8$; $n_{\text{males};32\text{weeks}} = 3-7$; $n_{\text{females};32\text{weeks}} = 4-7$). Areas under the curve were increased in HF mice (ANOVA diet effect: $p < 0.0001$, except males 32 weeks $p < 0.0003$) without any genotype effects.

The effect of *Dj-1* deficiency on glucose tolerance was additionally evaluated in mice fed a HF diet for 12 months and in male 8-month-old mice maintained on a high-fat, high-sugar diet (HF/HS, Appendix I.I Fig. A1) for 6 weeks (Fig. 3-28). We did not observe any differences in glucose tolerance of male or female *Dj-1*^{-/-} mice compared to their wildtype littermates.

Consequently, loss of *Dj-1* transiently influences insulin levels without affecting glucose tolerance.

Fig. 3-28. Intraperitoneal glucose tolerance test (i.p.GTT) of male (top) and female (bottom) *Dj-1*^{-/-} and *Dj-1*^{+/+} mice. After animals were deprived of food for 6 hours, they received an i.p. injection of 2 g glucose*kg⁻¹ body mass. Glucose was monitored in tail blood 15, 30, 60 and 120 min after glucose administration. (A, C) Mice at 6 weeks of age were placed on HF diet for 12 months (n = 4). For females, age matched chow-fed controls were available (n = 3-5), demonstrating a diet effect for areas under the curve (ANOVA p < 0.0001). (B, D) 8-month-old mice were placed on HF/HS diet for 6 weeks (n = 4). Values are means ± SD.

3.5 Influence of *Dj-1* deficiency on leptin sensitivity

The hormone leptin is produced and secreted by adipose tissue and plasma leptin levels positively correlate with body fat mass [Maffei et al. 1995]. In the central nervous system, the afferent leptin signal exerts an anorectic action representing a negative feedback mechanism for adiposity [Friedman & Halaas 1998]. Obesity, however, results in a state of leptin resistance with blunted central leptin action [Münzberg et al. 2004; Morrison 2008].

In *Dj-1*^{-/-} and *Dj-1*^{+/+} mice, leptin levels were increased by HF diet and significantly correlated with body fat mass in this diet group (Fig. 3-29). Because *Dj-1*^{-/-} mice showed an increased proportion of fat mass after 14 weeks of HF diet, we studied whether leptin sensitivity differs from their wildtype littermates.

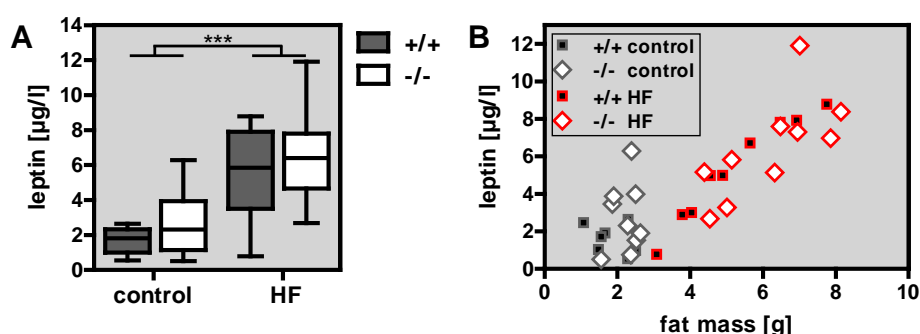

Fig. 3-29. Plasma leptin levels of male *Dj-1*^{-/-} and *Dj-1*^{+/+} mice maintained on HF or control diet for 14 weeks. (A) Plasma was collected from *ad libitum* fed mice (n = 8-10). ANOVA diet effect: ***p < 0.001. (B) Leptin levels related to fat mass. Leptin levels of HF diet-fed animals significantly correlate with fat mass (Pearson product-moment correlation: *Dj-1*^{+/+} r = 0.97, p < 0.0001; *Dj-1*^{-/-} r = 0.71, p = 0.0225).

3.5.1 Basal STAT3 phosphorylation is attenuated by high-fat diet in *Dj-1*^{-/-} mice

The activation of STAT3 to phospho-STAT3 is the most robust molecular marker of leptin action on the leptin receptor [Münzberg & Myers 2005] which is blunted in case of leptin resistance. We examined basal STAT3 signaling in lysates of the ventral hypothalamus of male *Dj-1*^{-/-} and *Dj-1*^{+/+} mice after 14 weeks of HF or control diet-feeding using western blot (Fig. 3-30 A). STAT3 levels positively correlated with phospho-STAT3 (Fig. 3-30 B). Total STAT3 levels were not significantly different between the genotype or diet groups (Fig. 3-30 C). However, phospho-STAT3 is significantly induced by HF diet in wildtype but not in *Dj-1*^{-/-} mice (Fig. 3-30 D). Furthermore, the ratio of phospho-STAT3 to STAT3 was affected by diet (Fig. 3-30 E). The tendency towards reduced phospho-STAT3/STAT3 ratios in *Dj-1*^{-/-} mice failed to reach statistical significance (p = 0.338). Consequently, wildtype mice are still

leptin sensitive after 14 weeks of HF diet-feeding while leptin sensitivity is lowered in *Dj-1^{-/-}* mice as judged by basal STAT3 phosphorylation.

Fig. 3-30. Basal STAT3 phosphorylation in male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice after 14 weeks of HF or control diet feeding. (A) Example western blot of protein extracts of the ventral hypothalamus. The three targets were detected on the same membrane. (B) Densitometric signals of total STAT3 and phospho-STAT3 were normalized to alpha-tubulin signals and plotted against each other. Pearson product-moment correlation between normalized phospho-STAT3 and STAT3 levels was significant. (C, D) Normalized total STAT3 and phospho-STAT3 levels. (E) Ratio of phospho-STAT3 to STAT3. ANOVA: significant effect of diet: * $p < 0.05$, Bonferroni post-test: # $p < 0.05$ HF vs. control diet. $n = 6-7$.

We next analyzed the inducible STAT3 phosphorylation after i.p. leptin administration in 6-month-old male *Dj-1^{-/-}* mice and their wildtype littermates maintained on a normal chow diet. Shortly before the onset of the dark phase, mice were injected with either $5 \text{ mg} \cdot \text{kg}^{-1}$ leptin or vehicle. The ventral part of the hypothalamus was taken 30 minutes after injection and subjected to western blot analysis (Fig. 3-31 A). While total STAT3 levels were unchanged (Fig. 3-31 B), leptin injection increased phospho-STAT3 levels approximately 4-fold compared to vehicle injection (Fig. 3-31 C). The magnitude is in accordance with previous reports showing a 3-fold increase of STAT3 phosphorylation in C57BL/6J mice one hour after i.p. leptin administration [Prpic et al. 2003]. Leptin-induced phospho-STAT3 levels as well as phospho-STAT3 to STAT3 ratios (Fig. 3-31 D) were comparable between *Dj-1^{-/-}* and *Dj-1^{+/+}* mice. Thus, the sensitivity towards exogenously applied leptin on the level of STAT3 phosphorylation is not affected in *Dj-1^{-/-}* mice under unchallenged conditions.

Fig. 3-31. Inducible STAT3 phosphorylation of 6-month-old *Dj-1^{-/-}* and *Dj-1^{+/+}* mice after i.p. leptin administration. 30 minutes after animals have received a leptin ($5 \text{ mg} \cdot \text{kg}^{-1}$) or vehicle injection, the ventral hypothalamus was dissected. (A) Western blot of protein extracts of the ventral hypothalamus. The three targets were detected on the same membrane. Densitometric signals of total STAT3 (B) and phospho-STAT3 (C) were normalized to alpha-tubulin signals. (D) Ratio of phospho-STAT3 to total STAT3 signals. Shown are the fold changes from *Dj-1^{+/+}* mice with vehicle injection. ANOVA: significant effect of treatment $***p \leq 0.0001$. $n_{\text{vehicle}} = 4$, $n_{\text{leptin}} = 6-7$.

3.5.2 Anorectic leptin action is similar in *Dj-1^{-/-}* and *Dj-1^{+/+}* mice

In addition to STAT3 phosphorylation, leptin sensitivity can be concluded from food intake inhibition in response to exogenous leptin [Scarpace & Zhang 2009]. We measured the anorectic response after i.p. injections of leptin in male HF and control diet-fed *Dj-1^{-/-}* and *Dj-1^{+/+}* mice to follow up whether the diminished leptin sensitivity implied on the level of STAT3 phosphorylation translates into a physiological effect. Towards the end of the 14- and 32-week feeding periods, mice received i.p. PBS administrations for three consecutive days followed by $5 \text{ mg} \cdot \text{kg}^{-1}$ leptin the day after. Injections were given shortly before the onset of the dark phase. Food intake was automatically recorded throughout the experiment. Leptin administration led to a decrease of cumulative energy intake in control diet-fed animals apparent after 12 hours (Fig. 3-32 A, C). The anorectic response was blunted in mice after 14 and 32 weeks of HF diet (Fig. 3-32 B, D) indicating HF diet-induced leptin resistance (Supplementary Fig. S7: time courses of cumulative energy intake). On both diets and after both time points, *Dj-1^{-/-}* mice did not differ from *Dj-1^{+/+}* mice in their anorectic response to leptin.

Fig. 3-32. 12-hour energy intake (EI) after i.p. leptin injection compared to PBS injection of male *Dj-1*^{-/-} and *Dj-1*^{+/+} mice maintained on HF or control diet for 14 or 32 weeks. Mice received i.p. PBS injection for three consecutive days followed by 5 mg*kg⁻¹ leptin the day after. Injections were given shortly before the onset of the dark phase. Energy intake was recorded automatically. Data points represent individual mice. Horizontal lines correspond to the mean. EI after PBS injection represents the mean of 3 days. ANOVA: effect of treatment *p < 0.05. n_{control} = 6-8, n_{HF} = 4-6.

3.6 High-fat diet has a greater impact on hypothalamic gene regulation in the absence of *Dj-1*

To further investigate the impact of the HF challenge on energy balance regulation in male *Dj-1*^{-/-} mice, we carried out a next generation sequencing-based transcriptome analysis of the ventral hypothalamus after 14 weeks of feeding. Groups were compared pairwise yielding a total of four comparisons: regulation by diet within wildtype mice or *Dj-1*^{-/-} mice and regulation by genotype within HF or control diet-fed groups. RNA expression analysis was performed with two different algorithms (DESeq and edgeR) applying a fold change of > 1.2 (upregulation) or < -1.2 (downregulation) with a p-value threshold of 0.05 corrected for multiple testing. Only hits significant for both algorithms were considered.

Using these criteria, HF compared to control diet-feeding did not lead to differential gene expression in the ventral part of the hypothalamus in neither wildtype nor *Dj-1*^{-/-} mice.

When *Dj-1*^{-/-} mice were compared to wildtype mice, 19 genotype-regulated genes were identified of which 12 were regulated under HF as well as under control diet conditions, 2 were only regulated under control diet and 5 only under HF diet (Table 3-12). Notably, 13 of these genes are localized on chromosome 4, where the *Dj-1* (*Park7*) gene is disrupted by a gene trap vector in *Dj-1*^{-/-} mice. Calculating the distance of these genes from *Dj-1* (*Park7*), the closest gene was located 64 kb upstream. All other genes were downstream of *Dj-1* with the closest located 648 kb and the furthest 5.5 Mb away (Supplementary Table S5).

Taken together, the *Dj-1* deficient genotype influenced the expression of ventral hypothalamic genes while the 14-week HF diet-intervention had no effect under these conditions.

Additional to the stringent statistical methods described above, we applied t-test statistics ($p < 0.01$ for log+1 transformed normalized expression values) combined with a read fold change of > 1.2 (upregulation) or < -1.2 (downregulation). The resulting lists contained all genes found differentially expressed using DESeq and edgeR algorithms. The highest number of regulated genes (332) was found for the comparison of *Dj-1*^{-/-} and *Dj-1*^{+/+} mice maintained on a HF diet (Fig. 3-33 B, Supplementary Table S9). This was followed by 239 regulated genes between HF and control diet-fed *Dj-1*^{-/-} mice (Fig. 3-33 A, Supplementary Table S7), 185 regulated genes between control diet-fed *Dj-1*^{-/-} and *Dj-1*^{+/+} mice (Fig. 3-33 B, Supplementary Table S8) and 146 regulated genes between HF and control diet-fed wildtype mice (Fig. 3-33 A, Supplementary Table S6). Regarding genes differentially expressed between HF and control diet-fed mice, only the transcription factor *Etv6* (ets variant gene 6 (TEL oncogene)) was regulated by diet in wildtype as well as in *Dj-1*^{-/-} mice while there were 22 genes commonly regulated by genotype in the control as well as in the HF group (Fig. 3-33; Supplementary Table S10). Of the common genotype

regulated genes, 14 were located on chromosome 4. Still, these results indicate that more genes are regulated when *Dj-1* deficiency is combined with HF feeding.

Table 3-10. Genotype-regulated genes under HF and control diet. Male *Dj-1*^{-/-} and wildtype mice were maintained on either HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed with both DESeq and edgeR algorithm ($p < 0.05$, adjusted). A log₂ fold change > 0.263 indicates upregulation and < -0.263 downregulation in *Dj-1*^{-/-} versus *Dj-1*^{+/+} mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively.

Fig. 3-33. VENN diagram summarizing the number of differentially expressed genes between *Dj-1^{-/-}* and *Dj-1^{+/+}* (wt) mice maintained on a high-fat (HF) or control diet for 14 weeks. Two groups were compared at a time. **(A)** Number of genes regulated by diet within wildtype or *Dj-1^{-/-}* mice. **(B)** Number of genes regulated by genotype within the control or HF diet-fed group. Differentially expressed genes are listed in Supplementary Tables S6-S10.

Using the extended candidate lists from the t-test statistic, we conducted a pathway analysis. We focused on pathways in the category ‘Diseases (MeSH)’ which we further subclassified into metabolic diseases (including obesity-concomitant phenomena) and diseases related to neurodegeneration or behavior.

Metabolic diseases

Regarding the regulation by diet, genes of seven pathways were overrepresented in both wildtype and *Dj-1^{-/-}* mice, whereby the number of regulated genes associated with these pathways was higher between HF and control diet-fed *Dj-1^{-/-}* compared to wildtype mice (Fig. 3-34 A, Supplementary Table S11). Further metabolic disease pathways were associated with diet-regulated genes in either wildtype or *Dj-1^{-/-}* mice. Only diet-regulated genes in *Dj-1^{-/-}* mice were significantly overrepresented in the pathways ‘Obesity/ Overweight/Overnutrition’ and ‘Body weight’ (Fig. 3-34 A) and, interestingly, the pathway ‘Mitochondrial Diseases’ was associated with the differential genes of this comparison.

Comparing *Dj-1^{-/-}* and wildtype mice, no differentially regulated genes were associated with metabolic disease pathways under control diet-feeding. Under the HF diet regime, several pathways were overrepresented by the genes differentially expressed between

Dj-1^{-/-} and *Dj-1^{+/+}* mice including three pathways linked to body weight regulation ('Body Weight', 'Weight Loss', 'Weight Gain'; Fig. 3-34 B, Supplementary Table S12).

(A) Regulation by diet

(B) Regulation by genotype

Fig. 3-34. Analysis of pathways associated with metabolic diseases. Shown are pathways for which differentially expressed genes between two groups compared at a time were significantly overrepresented. The length of the bars indicates the number of regulated genes contained in the respective pathway. Shown in parentheses is the number of total genes of the pathway. **(A)** Regulation by diet within wildtype mice (grey bars) or *Dj-1^{-/-}* mice (white bars). The regulated genes contained in the pathways 'Obesity', 'Overweight' and 'Overnutrition' are 100 % congruent. **(B)** Regulation by genotype within HF diet-fed groups (grey bars). No metabolic disease pathways were associated with the differentially expressed genes between control diet-fed *Dj-1^{-/-}* or *Dj-1^{+/+}* mice. See Supplementary Tables S11 and S12 for significance levels and lists of genes.

Diseases related to neurodegeneration or behavior

Genes differentially regulated by diet in wildtype mice were overrepresented in five pathways related to neurodegeneration or behavior while no pathway in this category was associated with diet-regulated genes in *Dj-1*^{-/-} mice (Fig. 3-35 A, Supplementary Table S13).

Comparing *Dj-1*^{-/-} and wildtype mice, genes of the pathway 'Demyelinating Disease' were overrepresented in both control and HF group being the only emerging pathway under control diet conditions in this category. In contrast, challenging *Dj-1*^{-/-} and *Dj-1*^{+/+} mice with a HF diet, genes of further seven pathways were significantly overrepresented in the genotype regulated genes (Fig. 3-35 B, Supplementary Table S14). This indicates that HF diet-feeding has a greater impact on mental health associated gene expression in the absence of *Dj-1*.

The length of the bars indicates the number of genotype regulated genes contained in the respective pathway. Shown in parentheses is the number of total genes of the pathway. **(A)** Regulation by diet within wildtype mice (grey bars). No pathways related to neurodegeneration were associated with the differentially expressed genes between control and HF diet-fed *Dj-1*^{-/-} mice. **(B)** Regulation by genotype within control diet (black bars) or HF diet-fed groups (grey bars). See Supplementary Tables S13 and S14 for significance levels and lists of genes.

3.7 The content of mitochondria is similar between $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice

Loss of $Dj-1$ is associated with increased mitochondrial H_2O_2 production in the mouse brain and, in older mice, upregulation of antioxidant enzymes [Andres-Mateos *et al.* 2007]. Furthermore, mitochondrial complex activities were increased in $Dj-1^{-/-}$ relative to wildtype mice [Pham *et al.* 2010]. Changes in these parameter could be due to an increased number of mitochondria. However, citrate synthase as a measure of mitochondrial content was either unchanged or increased in the brain of $Dj-1^{-/-}$ mice compared to wildtype mice [Andres-Mateos *et al.* 2007; Pham *et al.* 2010]. Here, we quantified the mitochondrial genome copy number relative to the nuclear genome copy number using a quantitative PCR with primers directed against exclusive nuclear or mitochondrial genomic targets. The mitochondrial copy number of male 18-week-old $Dj-1^{-/-}$ mice on control diet did not differ from their wildtype littermates neither in brain nor in gastrocnemius muscle or epididymal white adipose tissue (Fig. 3-36).

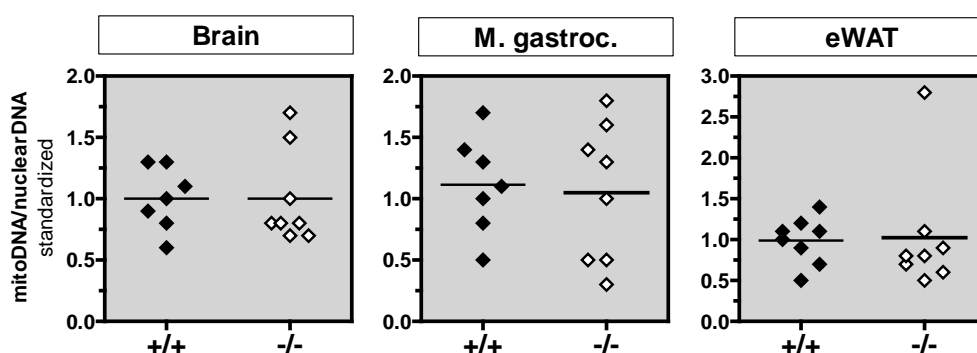

Fig. 3-36. Ratio of mitochondrial to nuclear DNA in the brain, gastrocnemius muscle (M. gastroc) and epididymal white adipose tissue (eWAT) of 18-week-old $Dj-1^{+/+}$ and $Dj-1^{-/-}$ mice.

4 DISCUSSION

4.1 Alterations in the hypothalamic proteome associated with a short-term high-fat diet intervention

The development of obesity is associated with changes in the homeostatic system of energy balance regulation in which the hypothalamus constitutes an important regulator of food intake and energy expenditure (see Chapter 1.2). Once obesity is established, the elevated level of adiposity is actively defended [Wisse *et al.* 2007; Leibel 2008]. In order to increase the understanding of how energy homeostasis is shifted out of balance during the development of overweight, we investigated changes occurring in the hypothalamus of mice after a 10-day HF diet intervention. We concentrated on changes that manifest on the protein level choosing a discovery-oriented proteomics approach and compared hypothalamic protein expression patterns between HF and control diet-fed mice of three strains differing in their susceptibility to DIO. HF diet-associated changes of protein abundances were small in number and extent but, interestingly, the number of candidates correlated positively with the level of adiposity detected in the different strains. In the complex network of energy balance regulation, numerous molecules are involved that orchestrate changes in response to nutritional stimuli. The contribution of individual components is probably small with changes expected to be less than three-fold [Mobbs *et al.* 2004]. On the other hand, we processed the complete hypothalamus which represents a complex tissue containing different cell types (neurons and glia) and highly specialized cells even within one cell population. Examining such a heterogeneous mixture including nuclei with opposing action (see Chapter 1.2.1) might neutralize effects of the applied intervention in specific cells. To attribute HF diet-induced effects on protein abundances to specific neuron populations, microdissection of the respective nuclei would have to be applied.

A small effect size of HF diet-feeding was also observed in a proteome study investigating the protein abundance in the hypothalami of male C57BL/6N mice after 18 weeks of HF feeding. In this study, an additional group of mice received a 'cafeteria' diet which contained higher amounts of simple sugars and salt. Interestingly, more proteins were differentially abundant in the hypothalami of mice fed the 'cafeteria' diet, although the diet-induced gain of body and fat mass was smaller compared to HF diet-fed mice (Supplementary Fig. S9, Supplementary Table 16). Thus, the diet-induced regulation of protein abundance or modification also depends on the type of diet.

Most prominently, DJ-1 (PARK7) was identified to be increased after 10 days of HF diet independently in all strains. In this experiment, we applied two-dimensional difference gel electrophoresis (2D-DIGE) as a quantitative method whereby different proteoforms⁸ are separated. The increase of DJ-1 corresponds to one form of DJ-1 (see discussion below) while the total DJ-1 content does neither change on the protein nor on the gene expression level. Gene expression levels of the remaining candidates⁹ were also not influenced by the HF diet intervention (Supplementary Table S2). This suggests that HF diet-feeding alters the proteome by post-translational mechanisms rather than transcription and protein synthesis. Unfortunately, it is difficult to identify potential protein modifications from 2D-DIGE analyses retrospectively because mass spectrometrical parameters for protein identification cannot be set for maximal sequence coverage for all proteins in the same run.

Nevertheless, several interesting relations between the regulated proteins become apparent when all candidates are summarized (Fig. 4-1; Table 3-1). Similar to *Dj-1*, mutations in the alpha-synuclein gene are associated with inherited PD [Thomas & Beal 2011]. Alpha-synuclein that was found less abundant in C57BL/6N mice upon HF feeding is a ubiquitous protein able to bind lipids and is involved in dopamine synthesis [Sharon et al. 2001; Perez et al. 2002]. Alpha-synuclein tends to aggregate, which is promoted by oxidative stress-induced posttranslational modification [Schildknecht et al. 2013; Xiang et al. 2013] and aggregated alpha-synuclein is a major component of Lewy bodies which are pathogenic inclusions characteristic of PD [Spillantini et al. 1997]. DJ-1 functions as a (co-)chaperone preventing the abnormal aggregation of alpha-synuclein in a redox-dependent manner [Shendelman et al. 2004; Zhou & Freed 2005; Zhou et al. 2006]. Moreover, beta-synuclein that was more abundant in HF diet-fed AKR/J mice inhibits alpha-synuclein aggregation [Hashimoto et al. 2001; Park & Lansbury 2003]. Thus, the upregulation or modification of DJ-1 and beta-synuclein might counteract alpha-synuclein aggregation which might be induced by changes in the redox state due to the HF diet-intervention (Fig 4-1).

Indeed, a redox-responsive protein was contained in the list of candidates: SH3 domain-binding glutamic acid-rich-like protein 3 (Sh3bgrl3) was more abundant in HF diet-fed AKR/J mice. It is a member of the thioredoxin family and implicated in cellular redox homeostasis through modulating the activities of glutaredoxins which are glutathione-dependent redox enzymes [Fernandes & Holmgren 2004; Nardini et al. 2004; Xu et al. 2005a]. This indicates that the redox milieu in the hypothalamus is influenced by the HF diet intervention.

⁸ This term summarizes 'the different molecular forms in which a protein product of a single gene can be found, including changes due to genetic variations, alternatively spliced RNA transcripts and posttranslational modifications' [Smith et al. 2013].

⁹ *Tcea15* was not included in the analysis.

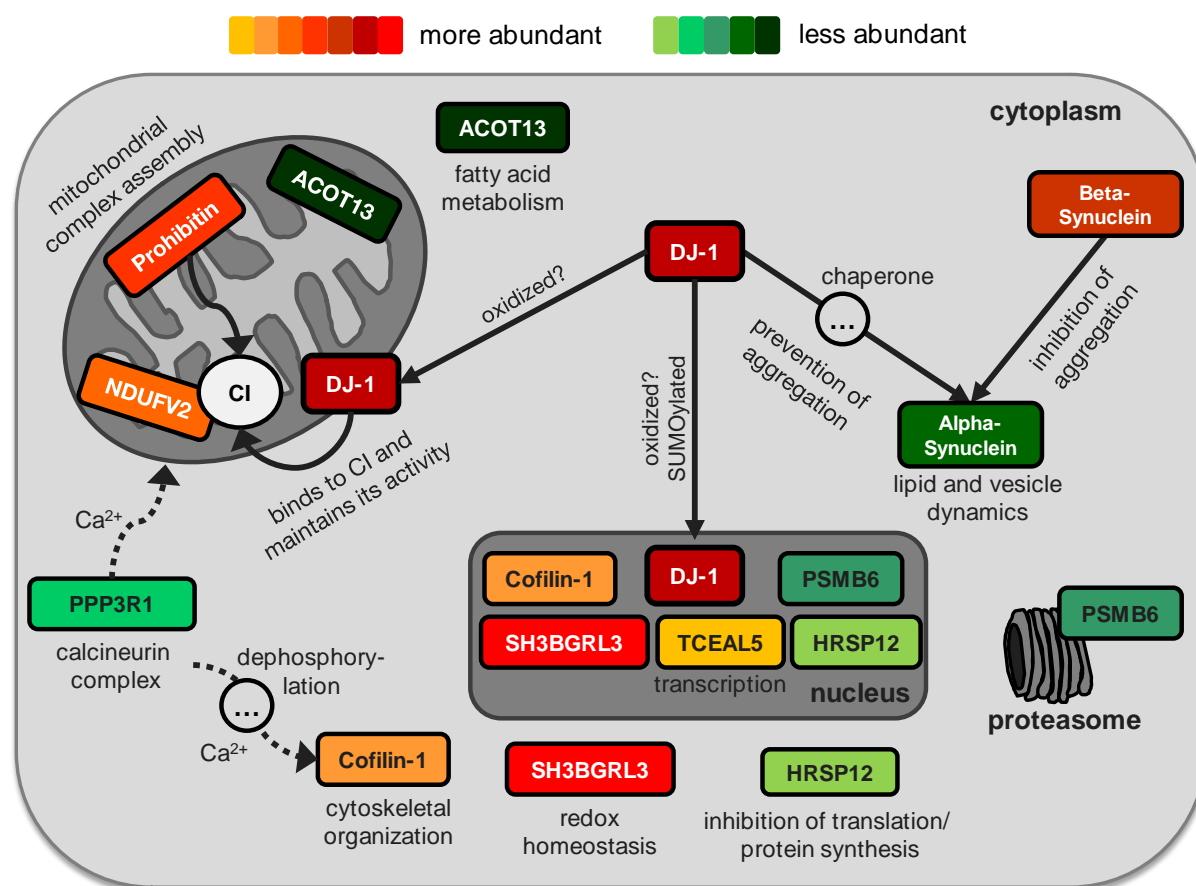

Fig. 4-1. Altered proteins in the hypothalamus of mice after 10 days of high-fat diet-feeding. Possible interactions of candidates arising from the comparison of protein expression patterns between HF and control diet-fed AKR/J, C57BL/6N and SWR/J mice are summarized (see Table 3-1). The subcellular localization is depicted as annotated in the UniProtKB database. The color code denotes the abundance of the proteoform in the HF compared to the control group. See text for further explanations. CI – Complex I. ACOT13 - Acyl-coenzyme A thioesterase 13. HRSP12 - Ribonuclease UK114. NDUFV2 - NADH dehydrogenase [ubiquinone] flavoprotein 2, mitochondrial. PPP3R1 - Calcineurin subunit B type 1. PSMB6 - Proteasome subunit beta type-6. SH3BGRL3 - SH3 domain-binding glutamic acid-rich-like protein 3. TCEAL5 - Transcription elongation factor A protein-like 5.

Mitochondria play an important role in regulating the intracellular homeostasis [Ryan & Hoogenraad 2007]. DJ-1 is able to translocate from the cytosol to the nucleus and mitochondria. Within mitochondria, DJ-1 can bind to complex I of the respiratory chain and maintain its correct function (Chapter 1.4) [Meulener et al. 2005a; Ved et al. 2005; Hayashi et al. 2009; Kwon et al. 2011]. Interestingly, one core subunit of complex I (Ndufv2) was more abundant in HF diet-fed SWR/J. Prohibitin, that was more abundant in HF diet-fed C57BL/6N mice, is a ubiquitous protein localized in the inner mitochondrial membrane. Prohibitin also interacts with complex I subunits (Fig. 4-1) [Bourges et al. 2004] and is involved in mitochondrial complex assembly [Nijtmans et al. 2002]. Furthermore, prohibitin is reduced in the substantia nigra of PD patients [Ferrer et al. 2007] and the enzymatic activity of complex I

is reduced in PD (reviewed in *Abou-Sleiman et al. [2006]*). Our results indicate that complex I function might also be important in the intracellular changes triggered by HF feeding and might be influenced by DJ-1.

Moreover, mitochondria play an important part in calcium homeostasis and signaling [*Rizzuto et al. 2000; Duchen et al. 2008*]. We found subunit B of calcineurin (Ppp3r1) less abundant in HF diet-fed AKR/J mice. Calcineurin is a Ca^{2+} - and calmodulin-dependent serine/threonine protein phosphatase that mediates cellular responses to intracellular Ca^{2+} signals and consists of a catalytic subunit A and the regulatory subunit B [*Rusnak & Mertz 2000*]. Calcineurin B has been shown to bind to mitochondria, suggesting further roles apart from regulating the catalytic activity of calcineurin A [*Cheng et al. 2012*].

Finally, cofilin-1 was found higher abundant in HF diet-fed AKR/J mice. Cofilin is a key regulator of actin filament dynamics which is activated by dephosphorylation in response to elevated ROS levels [*Kim et al. 2009a*] or intracellular Ca^{2+} levels [*Meberg et al. 1998; Birkenfeld et al. 2001*]. Calcineurin is indirectly involved in Ca^{2+} -induced cofilin activation [*Wang et al. 2005*].

In summary, a short-term HF diet-intervention influences the hypothalamic proteome by post-translational mechanisms that likely play an important part of the regulation. Altered proteins are implicated in mitochondrial function, especially related to complex I, as well as redox and calcium homeostasis. To our knowledge, none of the candidates have been shown to be influenced by HF feeding before. Notably, we demonstrate that some of the altered proteins are implicated in PD, suggesting an interaction or overlap of pathways involved in the development of obesity and neurodegenerative diseases.

4.2 High-fat feeding alters the isoform composition of the intracellular DJ-1 pool

DJ-1 undergoes several post-translational modifications and thus exists as a pool of isoforms differing in their pI [Natale et al. 2010]. Validation experiments showed that the composition of the DJ-1 pool is altered during HF diet-feeding with low pI isoforms becoming more abundant while more basic forms are decreased. For the hypothalamus, this finding was confirmed with three methods: two-dimensional gel electrophoresis (data not shown) and two IEF methods each of which were combined with semi-quantitative immunodetection of DJ-1.

Remarkably, a similar increase of low pI forms of DJ-1 has been observed in a variety of cells exposed to oxidative stresses such as hydrogen peroxide or paraquat and also in human brain samples under neurodegenerative conditions [Mitsumoto & Nakagawa 2001; Bandyopadhyay et al. 2004; Canet-Aviles et al. 2004; Kinumi et al. 2004; Taira et al. 2004; Zhou & Freed 2005; Choi et al. 2006; Kim et al. 2009b; Natale et al. 2010].

The pI of a DJ-1 isoform as detected by IEF does not certainly define the nature of modification. Murine DJ-1 contains 4 cysteines and 8 methionines which have the potential to undergo oxidation. The thiol group (-SH) of cysteines plays an important role in redox signaling as it can exist in a number of oxidation states: sulfenic (-SOH), sulfinic (-SO₂H), or sulfonic acid (-SO₃H) and as disulfide (-SS-) [Reddie & Carroll 2008; Paulsen & Carroll 2010]. In DJ-1, three cysteines are highly conserved (Cys-46, 53, 106) [Bandyopadhyay & Cookson 2004; Waak et al. 2009]. Oxidized cysteines have been identified in acidic DJ-1 isoforms, whereby Cys-106 is the most sensitive to oxidation (Fig. 4-2) [Wilson et al. 2003; Canet-Aviles et al. 2004; Kinumi et al. 2004; Zhou et al. 2006; Inden et al. 2011]. Cys-106 is critical for a number of functions of DJ-1. Mutations of this residue to other amino acids results in a loss of protective activity against oxidative stress in multiple systems [Canet-Aviles et al. 2004; Blackinton et al. 2009; Waak et al. 2009; Im et al. 2010; Madian et al. 2012]. The protective activity, however, seems to be dependent on the oxidation state since overoxidized DJ-1 is thermodynamically unstable [Hulleman et al. 2007], prone to aggregation [Zhou et al. 2006] and associated with aging and neurodegenerative diseases [Blackinton et al. 2009; Miyama et al. 2011; Wilson 2011]. Moreover, Cys-53 and Cys-46 are able to oxidize to a certain extent, disrupting the dimer formation [Kinumi et al. 2004; Waak et al. 2009] and methionine residues have been found oxidized to methionine sulfoxide [Choi et al. 2006; Lin et al. 2012].

Fig. 4-2. Oxidative modification of DJ-1 Cys-106 with increasing ROS level. The thiolate (S⁻) can react with H₂O₂ to form sulfenic acid (SOH). Further reactions with H₂O₂ leads to formation of sulfinic (SO₂H) and sulfonic (SO₃H) acid, which are regarded as irreversible oxoforms. The sulfinic acid of DJ-1 Cys-106 has been related to the cytoprotective activity of DJ-1, while further oxidation is linked to aging and neurodegenerative diseases. Modified from Paulsen & Carroll [2010] and Wilson [2011].

Our study is the first to report that an acidic shift of DJ-1 isoforms can be induced by HF diet-feeding in mouse tissue. We detected this phenomenon in the hypothalamus and brain stem, two brain areas that are direct targets for circulating adiposity signals or satiety signals transmitted through the vagus nerve or sympathetic fibers, respectively (Fig. 1-1) [Schwartz *et al.* 2000]. However, a comparable shift occurred in the cerebellum and forebrain, indicating that the whole brain is affected. Moreover, the isoform pattern was altered in liver, pancreas, and skeletal muscle. The latter two showed the most pronounced effect of all tissues investigated, with 5 or 6 of the 7 detected isoforms, respectively, being significantly changed due to HF diet-feeding. Interestingly, this effect was not present in white adipose tissue. Since DJ-1 is ubiquitously expressed, a tissue- or organ-specific role seems unlikely but might nevertheless result from cell-specific DJ-1 binding partners. However, the obtained data suggests that the HF diet-induced shift of the DJ-1 pool towards more acidic isoforms correlates with the metabolic rate of the tissue, which decreases in the order muscle >> brain > liver >> adipose tissue [Elia 1992] (no reference was found for pancreas). Although the brain almost exclusively utilizes glucose as energy supply [Peters *et al.* 2007], increased β -oxidation due to elevated fatty acid availability has been described for the hypothalamus [Lam *et al.* 2005]. Thus, DJ-1 modification might result from the HF diet-induced rise in β -oxidation along with a higher ROS production which is proportional to the metabolic activity of the organ.

The results listed above were detected after 10 days of HF diet-feeding. After two days of feeding, none of the DJ-1 isoforms were differentially abundant in the hypothalamus of HF or control diet-fed mice. After three months of HF diet-feeding, the increase of lower pI DJ-1

isoforms was observed in the hypothalamus but was less pronounced compared to the alterations after 10 days. However, due to high inter-assay coefficients of variation different runs cannot reliably be compared in a quantitative manner [Besong Agbo et al. 2013].

These results indicate that the composition of the DJ-1 pool does not change acutely due to the mere presence of increased fatty acid levels but rather depends on a marked increase in body fat or other attributes associated with DIO and possibly age. However, the influence of the duration of exposure to HF diet and/or age on the alteration of the DJ-1 pool composition might be different in other tissues. DJ-1 is also found in blood [Xu et al. 2010; Lin et al. 2012], which would be an interesting target for the evaluation of postprandial effects on DJ-1 modification.

We started to investigate whether the HF diet-induced shift of DJ-1 isoforms results from oxidation. First evidence indicates that the acidic isoforms likely represent indeed higher oxidized forms of DJ-1, as a comparable shift was observed when mouse brain lysate was treated with H₂O₂ (data not shown)¹⁰. Mass spectrometry based quantitative measurements of modified DJ-1 peptides were still ongoing at the time of writing this thesis.

It is still subject to debate, whether the oxidation of DJ-1 is reversible *in vivo* [Blackinton et al. 2009]. Reversibility of the acidic pI shift of DJ-1 was observed in mouse lung three hours after LPS treatment [Mitsumoto & Nakagawa 2001], in human neuroblastoma cells after paraquat was removed [Canet-Aviles et al. 2004] and in a human lung carcinoma cell line four hours after UV radiation [Shinbo et al. 2006], while DJ-1 oxidation could not be reversed in cultured human pneumocytes [Duan et al. 2008]. To date, no mechanism is known for the reduction of DJ-1Cys-106-SO₂. It was shown that it is not a substrate of sulfiredoxin that reduces cysteine sulfinic acids of peroxiredoxins which are antioxidant enzymes exerting their action through cysteine modification [Woo et al. 2005; Andres-Mateos et al. 2007; Blackinton et al. 2009; Paulsen & Carroll 2010]. Methionine sulfoxide can be reduced by the enzyme peptide methionine sulfoxide reductase [Weissbach et al. 2002]. Thus, if DJ-1 is functionally restored, it is probably cell-type specific and depends on the site and grade of oxidation or simply occurs by upregulation of protein synthesis and selective degradation of the oxidized form [Canet-Aviles et al. 2004; Duan et al. 2008].

Assuming that DJ-1 is present in higher oxidized forms in tissues of HF diet-fed mice, we can speculate that high fat intake increases the generation of ROS *in vivo*. We manipulated the cellular redox capacity by supplementing the drinking water with N-acetylcysteine (NAC) to test if this influences the DJ-1 pool composition. NAC increases the redox capacity through elevating glutathione, which represents an important antioxidative system in the cell [Fujii et al. 2011]. Furthermore, NAC is able to penetrate cell membranes and cross the blood-brain barrier resulting in repletion of neuronal glutathione content [Farr et

¹⁰ Experiments were carried out by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

al. 2003; Berman et al. 2011]. We observed an increase in both reduced and oxidized glutathione in the brain and muscle after NAC treatment to comparable levels between HF and control diet-fed mice. The effect of NAC treatment on the formation of lower pI isoforms of DJ-1 was tested in the hypothalamus using the gel-based IEF method. The result was similar to what was obtained from the comparison of HF and control mice without NAC treatment suggesting that elevated glutathione levels do not influence DJ-1 oxidation at least in the hypothalamus. This experiment should be confirmed with the capillary IEF immunoassay, which is more sensitive and detected higher changes under basal conditions.

Previously, conflicting results were reported regarding the influence of HF diet-feeding on hypothalamic glutathione levels: GSH levels were increased in mice after three days of HF diet-feeding [*Jaillard et al. 2009*] while the GSSG-to-GSx ratio was twice as high in genetically obese compared to lean rats [*Colombani et al. 2009*]. In our study, glutathione levels were comparable between HF and control diet-fed mice in the brain and hypothalamus (data not shown) speaking against a connection of DJ-1 oxidation and glutathione homeostasis. In contrast, GSH was elevated by HF diet-feeding in the gastrocnemius muscle, the tissue in which the alteration of the DJ-1 pool was most pronounced. It was reported that DJ-1 increases GSH levels during oxidative stress through upregulation of glutamate cysteine ligase transcription and activity, which is involved in glutathione synthesis [*Zhou & Freed 2005*]. This function of DJ-1 was not directly shown to be dependent on its oxidation state but DJ-1 oxidation is enhanced when glutathione synthesis is inhibited and GSH levels drop [*Miyama et al. 2011*]. However, the transcription of glutamine cysteine ligase is regulated by several molecules [*Fujii et al. 2011*]. We suppose that oxidized DJ-1 and the supply of reduced glutathione act in parallel rather than in series to regulate redox homeostasis. Thus, it would be of interest to examine the DJ-1 isoform pattern in muscle after NAC treatment which resulted in elevated glutathione levels that were not longer different between HF and control diet-fed mice.

Within a cell, the cytosol contains most of the DJ-1 pool, but it is also found in the nucleus as well as mitochondria [*Nagakubo et al. 1997; Taira et al. 2004; Zhang et al. 2005a*]. Translocation to these two compartments is enhanced in response to oxidative stimuli and it was suggested that cysteine sulfinic acid formation at Cys-106 might be important but not necessarily required for the association of DJ-1 with mitochondria [*Canet-Aviles et al. 2004; Blackinton et al. 2005; Li et al. 2005; Lev et al. 2008; Blackinton et al. 2009; Junn et al. 2009*]. Here, we investigated the isoform distribution in cytosolic and mitochondrial fractions obtained from brain tissue of HF or control diet-fed mice. As expected, total signal intensities were lower in mitochondrial compared to cytosolic fractions. In mitochondria, one main isoform (pI 6.2) was observed, while other isoforms can hardly be detected. This indicates that heavy oxidation of DJ-1 is not a prerequisite to enable mitochondrial translocation. Regarding the individual

DJ-1 isoforms, no differences between HF and control diet-fed mice were observed in either cytosol or mitochondria. This result seems to contradict data obtained from whole tissue. However, the fractionation process involved several centrifugation steps, different buffers were used and protease and phosphatase inhibitors were not present from the beginning - factors which might influence protein modifications. Thus, the result cannot be directly compared to whole tissue. Nevertheless, a tendency towards decreased total DJ-1 content in mitochondria from HF diet-fed mice was observed using conventional western blot analysis as well as the capillary IEF (Fig. 3-11 C and 3-12 F). This finding suggests that the stimulus responsible for mitochondrial translocation is reduced in the brain upon HF feeding. We did not pay attention to the isoform distribution in the nucleus which might be interesting to investigate in future studies.

Finally, it is of interest what consequences the DJ-1 modifications in the context of HF feeding have. It is regarded unlikely, that DJ-1 possesses enzymatic activity [*Honbou et al. 2003; Wilson et al. 2003; Shendelman et al. 2004; Gorner et al. 2007*]. We and others show that acidic (oxidized) DJ-1 forms are present under physiological conditions indicating that severe oxidative stress is not required for oxidative modification [*Mitsumoto & Nakagawa 2001; Duan et al. 2008*]. We observed the HF diet-induced isoform shift of DJ-1 in the brain and peripheral tissues. Possibly, oxidation of DJ-1 is a response to ROS produced during aerobic metabolism [*Mitsumoto & Nakagawa 2001*], which might be increased due to the systemic fatty acid overload. Oxidized or otherwise modified DJ-1 might then enable to adapt to the changed metabolic situation through several possible mechanisms: the interaction with proteins to regulate their activity or shuttling them to their place of action within the cell or through regulation of transcription (Fig. 4-3).

We analyzed the hypothalamic gene expression of several candidates known to be regulated by DJ-1 or affected by its absence. Of these genes, none were regulated by HF diet on transcript level in our mouse model (Supplementary Table S2). DJ-1 might yet affect other genes in response to HF diet-feeding. Furthermore, we co-immunoprecipitated direct or indirect DJ-1 binding partners from brain lysate of HF or control diet-fed mice¹¹ (Supplementary Table S15). Subsequent mass spectrometrical quantification revealed no differences in the protein abundances of co-precipitated proteins between the diet groups. Regarding the above hypothesis, the influence of HF diet-feeding on DJ-1 protein interaction is probably not due to stable binding but rather to temporary interaction influencing protein modifications.

¹¹ The experiment was conducted by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

Overall, DJ-1 might constitute a sensor of the cellular redox state [Wilson 2011] with oxidation as a key regulatory modification relaying this information on to signaling pathways aiming to restore cellular homeostasis and adapt to altered metabolic situations.

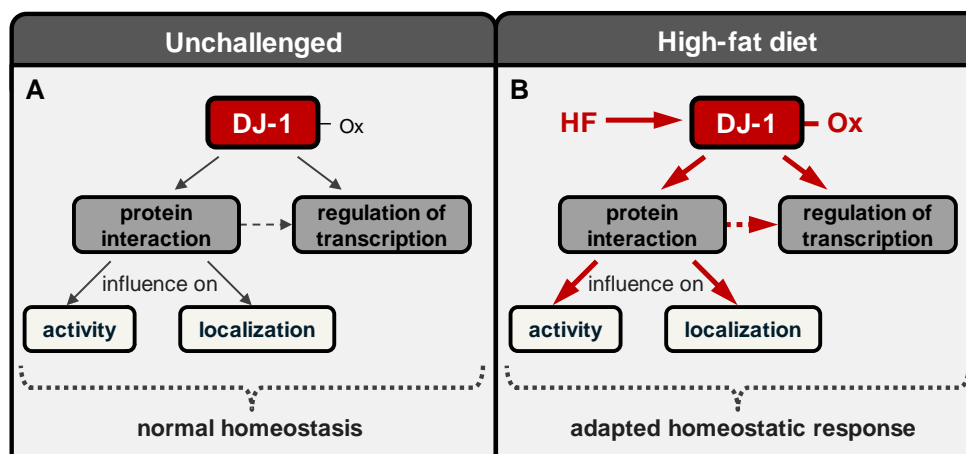

Fig. 4-3. Proposed mechanism of metabolic adaptation to nutrient abundance in the presence of DJ-1. (A) Under unchallenged conditions, a small amount of the DJ-1 pool is oxidized which can interact with other proteins to influence their activity or localization within the cell and regulate transcription directly or indirectly. Thereby, DJ-1 contributes to the maintenance of normal cellular homeostasis. (B) High-fat (HF) diet-feeding increases DJ-1 oxidation leading to enhanced DJ-1 action which helps to adapt the homeostatic system to the changed metabolic situation.

4.3 Brain mitochondria from high-fat diet-fed mice function normally

Obesity in humans is associated with increased systemic oxidative stress levels [Keaney *et al.* 2003; Vincent & Taylor 2006; Vincent *et al.* 2007]. We speculate that a change in the redox state is responsible for the HF diet-induced increase of acidic DJ-1 isoforms *in vivo*. Mitochondria release ROS as a physiological consequence of oxidative phosphorylation and several genes implicated in mitochondrial functions were regulated in the hypothalamus in the initial proteome study. Thus, we examined the generation of ROS in isolated brain mitochondria from mice fed a HF or control diet for 10 days. Hydrogen peroxide production rates were similar between the diet groups in the crude mitochondrial fraction as well as in mitochondria treated with sodium carbonate which detaches loosely associated proteins and represent a cleaner fraction (see Chapter 2.8, data not shown). However, mitochondria have been isolated from their physiological context, which might not necessarily allow a conclusion towards ROS production *in vivo* under the specific conditions induced by HF diet-feeding. Characterizing isolated mitochondria from HF and control diet-fed mice *ex vivo* rather shows

that they have the capability to function normally. Furthermore, cells contain other sources of ROS like NADPH oxidases which produce superoxide by transferring electrons from NADPH to molecular oxygen. NADPH oxidase-linked ROS generation is increased in the cerebral cortex of diet-induced obese rats [Zhang et al. 2005b]. We applied a method to detect ROS on the tissue level using a membrane-permeable dye which becomes fluorescent upon the reaction with hydrogen peroxide [Benani et al. 2007]. As before, hypothalamic ROS levels were not different after 10 days of HF diet as compared to controls [Schöttl 2011].

Moreover, the protein abundance of the antioxidant enzyme SOD2 did not differ between HF and control diet-fed mice which is in line with the unchanged ROS production. However, studies on human cells suggest that few if any antioxidant enzymes are regulated by hydrogen peroxide [Chuang et al. 2002; Weigel et al. 2002; Desaint et al. 2004].

Taken together, our data provide no evidence for altered ROS levels in the brain upon HF feeding. However, these results do not contradict our hypothesis that the HF diet-induced acidic DJ-1 isoform shift is due to changes in the redox state. Although ROS are generally regarded as a source of 'oxidative stress' able to damage macromolecules, an important part of ROS activity is exerted through their action on signaling pathways [Maher & Schubert 2000]. Within the hypothalamus, ROS play a role in glucose and lipid sensing [Leloup et al. 2006; Benani et al. 2007; Colombani et al. 2009] as well as in insulin-induced food intake inhibition [Jaillard et al. 2009]. The action of H₂O₂ as a second messenger to modulate protein function is likely locally restricted. As an example, H₂O₂ is generated in the vicinity of stimulated cell surface receptors and molecules that diffuse away from this place of action are rapidly destroyed [Rhee et al. 2000; Paulsen & Carroll 2010]. Measuring the overall H₂O₂ production, thus, is not very conclusive with regard to local concentrations.

Our data provide evidence that brain mitochondria function normally in the presence of increased systemic fatty acid levels. Thus, adaptation mechanisms towards altered substrate supply *in vivo* are thus of a physiological rather than pathophysiological nature.

4.4 Differences in phenotypic parameters of high-fat diet challenged *Dj-1*^{-/-} compared to wildtype mice

Several mutations of the human *DJ-1* gene have been associated with inherited forms of PD [Bonifati et al. 2003b]. Surprisingly, none of the *Dj-1* mutant mouse lines resemble the typical PD phenotype with an age-dependent degeneration of dopaminergic neurons in the substantia nigra [Chen et al. 2005; Goldberg et al. 2005; Kim et al. 2005b; Andres-Mateos et al. 2007; Pham et al. 2010] and only minor motor deficits [Chen et al. 2005; Chandran et al. 2008]. However, DJ-1 is not only expressed in the brain and its molecular functions are very diverse due to the ability to interact with numerous proteins as well as with RNA, a feature that is influenced by changes in the redox state in many cases (see Chapter 1.4).

In this study, DJ-1 emerged as a candidate protein from the comparison of the hypothalamic proteome in response to a short-term HF or control diet intervention. Other proteome studies found DJ-1 upregulated by HF diet and hyperglycemic stimulation in mouse pancreatic islets of Langerhans [Waanders et al. 2009] or downregulated in the epididymal white adipose tissue (eWAT) of obese rats [Joo et al. 2011]. We therefore investigated the gene-diet interaction in *Dj-1* deficient mice (*Dj-1*^{-/-}) in order to elucidate the physiological function of this protein in energy balance regulation.

Increased fat accumulation in high-fat diet challenged *Dj-1*^{-/-} mice

After 14 weeks of HF-feeding, the body composition of *Dj-1*^{-/-} mice was altered compared to wildtype littermates favoring higher fat accumulation at the expense of lean mass leaving the body mass unchanged. Assessing the level of DIO, body mass is most commonly focused on as the most important outcome, while the body partitioning is often neglected. However, the divergence of energy intake from energy expenditure over time can also be reflected by the relative amounts of fat and lean mass. Since these components show an almost 10-fold difference in their energy density, large shifts in body energy content can occur without altering the body mass [Leibel 2008]. Although ANCOVA analysis revealed a higher adiposity in both male and female mice after 14 weeks of HF diet, the level of DIO was much less pronounced in females. In our study, female wildtype mice placed on a HF diet at the age of 4 weeks were protected from DIO for the first 14 weeks after which they started to gain considerable amounts of fat with ongoing HF diet-feeding confirming sex-specific differences in the response to a HF diet [Hwang et al. 2010]. The differences in adiposity between male *Dj-1*^{-/-} and *Dj-1*^{+/+} mice were counterbalanced with ongoing HF-feeding. In contrast, female mice showed a higher HF diet-induced fat mass for the subcutaneous depot after 32 weeks of feeding. Probably, the counterbalancing is delayed in female mice and might be fat depot-dependent. Notably, muscle wet weights were reduced in aged male and female *Dj-1*^{-/-} mice

independent of diet. It was formerly reported that the body mass of male *Dj-1^{-/-}* mice was similar to wildtype mice in the first year after which it decreased progressively with age [Chandran *et al.* 2008]. Since body composition was not measured in this study, possibly, a reduced lean mass is causative for the reduced body mass observed in old *Dj-1^{-/-}* mice.

The prolonged feeding, however, was conducted with a smaller sample size. During the 32 weeks of HF-feeding, approximately one third of the mice of both sexes did not respond to the HF diet. Animals were categorized as non-responders if their fat mass after 32 weeks of HF diet was not raised above twice the mean of control diet-fed mice (Supplementary Fig. S4) and thus were excluded from further analyses. We can exclude a litter effect because all obesity resistant mice originated from different litters with the size ranging from 3 to 9 pups which was representative of the overall litter size distribution (Supplementary Fig. S3). The percentage of DIO resistance is in accordance with a previous observation showing that 35 % of male C57BL/6J mice fed a HF diet for 20 weeks maintain a body mass comparable to chow diet-fed mice [Enriori *et al.* 2007].

Glucose tolerance tests and further measurements were performed during the last two weeks of the feeding periods, which resulted in a slight drop of fat mass and/or body mass (Fig. 3-18 and 3-21). However, altered body composition was already present after 12 weeks of HF diet (Supplementary Fig. 5-6), so we can exclude the possibility that this phenotype is due to differences in susceptibility towards stress.

We conclude that the increased adiposity of HF diet-fed *Dj-1^{-/-}* mice is a transient effect more pronounced during the development and adaptation phase to the HF diet. On the other hand, the decrease in muscle mass becomes distinct with higher age independent of diet. Having shown that the HF diet-induced modification of DJ-1 is most pronounced in skeletal muscle, the role of DJ-1 in this tissue should be focused on in future studies.

***Dj-1* deficient mice are hypoactive without detectable changes in energy intake and energy expenditure**

We studied which component of energy metabolism contributes to the altered body composition in male *Dj-1^{-/-}* mice. Energy intake and metabolic rate were comparable in *Dj-1^{-/-}* and *Dj-1^{+/+}* mice. However, *Dj-1^{-/-}* mice gained ~1 g more adipose tissue than wildtype mice within 14 weeks of HF diet. Neglecting lean mass and assuming 29 kJ energy per gram fat [Klaus 2004], the difference amounts to 0.3 kJ per day. This translates into 0.7 % less energy expended (of 46 kJ/day) or 14 mg food consumed more by *Dj-1^{-/-}* mice on a daily basis. To reliably detect such a small difference, the employed methods are not precise enough.

Energy expenditure is influenced by body mass as well as body composition, which has to be corrected for. We chose to normalize our data to body composition taking into account the differing metabolic activity of fat and lean tissue [Even & Nadkarni 2012] because this

method eliminates the body mass dependency (Fig. 3-25). When normalized to body composition, basal metabolic rate ($HP_{30^{\circ}C,pa}$) was increased in female $Dj-1^{-/-}$ mice after 32 weeks of control diet-feeding and by tendency in male $Dj-1^{-/-}$ mice after 14 weeks HF diet-feeding. Notably, these are the groups in which $Dj-1^{-/-}$ mice displayed higher adiposity. A higher basal metabolic rate in the presence of less metabolic active tissue could be an explanation of the transience of the body composition phenotype.

Parameters of nocturnal spontaneous activity were decreased in $Dj-1^{-/-}$ mice compared to wildtype mice on control diet while the activity of HF diet-fed mice was comparable between the genotypes. Thus, HF feeding results in a drop of activity in wildtype mice but does not decrease further in $Dj-1^{-/-}$ mice. These results were obtained after 14 weeks of feeding. Analysis of activity in HF diet-fed mice after 32 weeks of feeding was inconclusive due to low animal numbers after exclusion of obesity-resistant mice. In male control diet-fed $Dj-1^{-/-}$ mice, however, we also observed a lower activity level compared to wildtype mice at this age (Supplementary Table S4). In female mice, no significant genotype differences were detected at this age due to very high inter-individual variation. Hypoactivity of $Dj-1$ deficient mice has been reported before as diminished horizontal and rearing activity [Goldberg *et al.* 2005; Pham *et al.* 2010]. Furthermore, old $Dj-1^{-/-}$ mice display reduced grip strength without any differences in gross muscle anatomy [Chandran *et al.* 2008]. Notably, our study shows that the reduced activity of $Dj-1^{-/-}$ mice is associated with a reduced lean mass. Yet, whether the reduced muscle mass is causative or a consequence of the hypoactivity needs further clarification. In favor of the first possibility is the fact that DJ-1 is linked to the regulation of calcium homeostasis in isolated mouse skeletal muscle cells [Shtifman *et al.* 2011]. Loss of $Dj-1$ leads to elevated resting intracellular Ca^{2+} concentrations and decreased Ca^{2+} release from the sarcoplasmic reticulum in response to electrical stimulation, both of which are partially reversed by the antioxidant glutathione or by activating mitochondrial function using resveratrol [Shtifman *et al.* 2011]. Calcium flux, however, is not only crucial for muscle contraction but also stimulates the synthesis of dopamine in neurons of the substantia nigra which are degenerated in PD (reviewed in Surmeier *et al.* [2011]). Whether loss of $Dj-1$ similarly disrupts calcium homeostasis in the central nervous system remains to be shown. In summary, the increased adiposity and decreased muscle mass in $Dj-1^{-/-}$ mice after 14 weeks of HF diet-feeding cannot be explained by the energy intake or energy expenditure measurements. Hypoactivity of $Dj-1^{-/-}$ mice likely contributes to this phenotype but this is obviously compensated under control diet conditions where adiposity is similar to wildtype mice. Possibly, an increased basal metabolic rate serves as a mechanism counter-regulating the altered body composition explaining the transience of this phenotype.

***Dj-1* deficiency influences glucose levels without affecting glucose tolerance**

Altered relative amounts of fat and lean mass may influence glucose metabolism. After 14 weeks of HF or control diet-feeding, we found altered plasma glucose levels in *ad libitum* fed male mice which were dependent of genotype and diet. Wildtype mice maintained similar glucose levels under HF and control diet but in order to do so produce, by trend, higher amounts of insulin under HF diet. Conclusively, HF diet-feeding induced insulin resistance of peripheral tissues which is reflected in increased HOMA-IR levels (not significant). Compared to wildtype mice, control diet-fed *Dj-1*^{-/-} mice have slightly lower glucose levels but in the presence of higher insulin levels. This indicates that *Dj-1* deficiency negatively influences peripheral insulin sensitivity already under control diet conditions. HF diet-challenge does not further increase insulin levels in *Dj-1*^{-/-} mice but they are not sufficient to retain normal glucose levels as is the case in wildtype mice. HOMA-IR indices on the other hand suggest that HF diet-feeding did not further aggravate insulin resistance in *Dj-1*^{-/-} mice. Insulin and HOMA-IR data, however, were not statistically significant due to high intra-group variability. This might be due to the fact that blood was taken from non-fasted mice although the time window of blood collection did not exceed 3.5 hours during the day time. The trend towards attenuated insulin sensitivity in unchallenged *Dj-1*^{-/-} mice regressed with age as this effect was not detected after 32 weeks of feeding.

Moreover, glucose clearance measured in an i.p. glucose tolerance test was comparable between *Dj-1*^{-/-} or *Dj-1*^{+/+} mice regardless of diet or age. Previously, a decreased glucose tolerance in male *Dj-1*^{-/-} mice at 12-13 weeks of age and in 8-week-old mice after two weeks of HF diet was described [Jain *et al.* 2012]. The glucose tolerance test differed from ours in the length of fasting before glucose injection (overnight vs. 6 hours), the diets used and the mouse model. In this publication, the impaired glucose tolerance in HF diet-fed *Dj-1*^{-/-} mice was accompanied by a blunted increase of insulin secretion 40 min after glucose injection and this finding was linked to a reduced β -cell area in *Dj-1*^{-/-} mice [Jain *et al.* 2012]. Considering this, we speculate that a period of peripheral insulin resistance with higher insulin secretion leads to the exhaustion and finally decay of β -cells comparable to type 2 diabetic patients and that this development might be accelerated in *Dj-1*^{-/-} mice. However, HF diet-feeding for 32 weeks resulted in higher absolute values of plasma insulin levels without any genotype differences (Table 3-9). This suggests that *Dj-1*^{-/-} mice can produce the same amount of insulin with a lower number of β -cells but this theory needs to be proven in further experiments.

Taken together, we suggest that peripheral insulin resistance in *Dj-1*^{-/-} mice coincides with the altered body composition observed after 14 weeks of HF feeding and that both phenotypes are transient effects.

***Dj-1* deficiency does not influence anorectic leptin action**

Another aspect observed in the pathophysiology of obesity is the loss of sensitivity towards leptin, a hormone secreted in proportion to the body fat stores [Maffei *et al.* 1995; Considine *et al.* 1996; Schwartz *et al.* 1996]. In the central nervous system, the afferent leptin signal exerts anorectic action representing a negative feedback mechanism for adiposity [Friedman & Halaas 1998]. In a state of leptin resistance, the central leptin action is blunted resulting in the disturbance of the negative feedback loop [Münzberg *et al.* 2004; Münzberg & Myers 2005; Scarpace & Zhang 2009]. Having shown that *Dj-1*^{-/-} mice accumulate more fat within 14 weeks of HF diet, we studied whether they differ in leptin sensitivity from their wildtype littermates. HF diet-fed wildtype mice displayed elevated phospho-STAT3 levels in the ventral hypothalamus compared to control diet-fed mice and by tendency a higher phospho-STAT3 to total STAT3 ratio. Since leptin levels are increased in HF diet-fed animals and STAT3 is phosphorylated upon leptin receptor activation, this indicates intact leptin signaling after 14 weeks of HF diet in wildtype mice. In contrast, HF diet-fed *Dj-1*^{-/-} mice displayed phospho-STAT3 levels comparable to control diet-fed mice. This result suggests that in HF diet-fed *Dj-1*^{-/-} mice the magnitude of the central response to circulating leptin levels is lower compared to wildtype mice.

Hence, we tested whether the physiological anorectic response to exogenous leptin is affected in *Dj-1*^{-/-} mice. In control diet-fed animals, the energy intake in the dark phase following i.p. leptin administration was reduced to a similar extent in wildtype and *Dj-1*^{-/-} mice. The anorectic response was attenuated in mice of both genotypes after 14 and 32 weeks of HF diet indicating comparable levels of leptin resistance.

Leptin reduces food intake in lean animals during a time window of 2 to 12 hours after application [Myers *et al.* 2010]. In our study, the mean decrease in energy intake 12 hours after i.p. leptin administration ranged from 14 to 20 % in control diet-fed mice (as compared to energy intake after PBS injections). This magnitude is similar to previous observations in male C57BL/6 mice showing a reduction of 25 % after administration of 2 mg*kg⁻¹ leptin on two consecutive days [Enriori *et al.* 2007] or a decrease of 11 % after the injection of 10 mg*kg⁻¹ leptin on three consecutive days [van Heek *et al.* 1997]. The average leptin-induced reduction of energy intake in HF diet-fed mice was 10-11 % after 14 weeks of feeding. A similar effect size was reported after 11 weeks of HF diet-feeding in male mice (13 % after 2 mg*kg⁻¹ leptin for 3 days) [Kleinridders *et al.* 2009]. After 32 weeks of HF-feeding, mice showed only a mean reduction in energy intake of 4 %. Obviously, a long period of HF feeding is required for the manifestation of leptin resistance in our DIO mouse model.

We observed a very high intra-group variability and high variability between the nocturnal food intake of individual mice. Due to textural differences, the spillage is much higher for HF compared to control diet and this could not be corrected for. For this reason,

mice had to be excluded resulting in low animal numbers. To obtain sufficient animal numbers in the HF groups, this was the only experiment in which obesity-resistant mice were included. They showed a stronger reduction in food intake after leptin injection indicating that leptin signaling is intact (Supplementary Fig. S8). Thus, the difference in energy intake between HF and control diet-fed mice is likely to be higher if the HF group consisted of only obesity-prone mice. Moreover, this indicates that leptin resistance is dependent on body mass and not solely on fat as a dietary constituent as has been suggested before [Banks et al. 2004]. Finally, we administered leptin only once. The anorectic response to leptin might be less heterogeneous when leptin is applied repeatedly as in the other studies [van Heek et al. 1997; Enriori et al. 2007; Kleinridders et al. 2009].

Although STAT3 phosphorylation was higher in HF diet-fed wildtype mice compared to *Dj-1^{-/-}* mice, the anorectic response to exogenous leptin was not different. However, basal STAT3 phosphorylation does not necessarily mirror inducible phospho-STAT3 levels upon exogenous leptin administration. Although leptin-induced STAT3 phosphorylation was similar in unchallenged *Dj-1^{-/-}* and *Dj-1^{+/+}* mice, this remains to be tested in HF diet-fed animals.

Conclusively, loss of *Dj-1* does not influence leptin sensitivity in unchallenged mice and it seems unlikely that it does so under HF conditions.

4.5 High-fat diet has a greater impact on hypothalamic gene regulation in the absence of *Dj-1*

Multiple proteins sense and mediate the various peripheral signals implicated in the regulation of energy balance [Leibel 2008]. Moreover, the central response to signals like leptin is mediated through more than one pathway [Myers et al. 2008]. We therefore chose an unbiased approach to identify factors involved in energy balance regulation and performed a transcriptome analysis of the ventral hypothalamus comparing HF or control diet fed *Dj-1*^{-/-} and *Dj-1*^{+/+} mice. This part of the hypothalamus includes the arcuate nucleus (ARC) and ventromedial nucleus, two main areas involved in energy homeostasis and satiety. The four experimental groups were compared pairwise and the results separated into regulation by diet or regulation by genotype.

Using very stringent statistical methods, no genes were differentially expressed between HF and control diet-fed mice. Possibly, there is a stronger effect in earlier phases during HF diet-feeding but once the body is adapted to the new metabolic situation and defends the state of adiposity [Wisse et al. 2007; Leibel 2008], the influence of HF diet on gene expression decreases. Regarding the genes regulated by genotype in both diet groups, a substantial amount (70 %) locate to chromosome 4 which harbors the *Dj-1* (*Park7*) gene that was disrupted by the introduction of a gene trap vector in *Dj-1*^{-/-} mice. There are two possible explanations for this: First, this might be an allele effect resulting from the generation of *Dj-1*^{-/-} mice. ES cell clones were derived from the 129P2/OLaHsd mouse strain, injected into blastocysts of C57BL/6J mice and resulting chimeras were mated with C57BL/6J mice generating heterozygous mice [Pham et al. 2010]. Theoretically, every round of backcrossing with C57BL/6J wildtype mice reduces the heterozygosity by 50 %. Mice used in this study had been backcrossed onto C57BL/6J background for 11 generations leaving only 0.1 % of the genome heterozygous. However, this is only true for those parts of the genome that are not in high linkage disequilibrium with the differential gene. Since the *Dj-1* locus is the selection criteria during breeding, loci in high linkage disequilibrium with this locus are also selected for. Thus, the heterozygosity of this region has to be regarded more critical compared to the rest of the genome.

Second, this region might represent a functional gene cluster and the insertion of the gene trap vector into the *Dj-1* locus disrupts a cis-regulatory element of these genes. In this case, effects attributed to the loss of *Dj-1* rather have to be interpreted as the combined effect of several genes. Moreover, conclusions regarding the function of *Dj-1* drawn from this mouse model cannot be transferred to other species, since i.e. in humans *DJ-1* is located on chromosome 1.

Considering that comparing 4-5 animals per genotype-diet group does not have a high statistical power, we reanalyzed the transcriptome data using simple t-tests in order to extend the list of possible candidates. Although we are aware that the false positive rate may be high (and thus, individual genes shall not be discussed), this less stringent statistical approach led to an interesting finding considering the number of regulated genes. Overall, we observed a higher number of genes to be regulated by genotype within the diet groups than by diet within genotype comparisons. Prominently, the combination of *Dj-1* deficiency and HF diet showed the greatest effect on gene expression: The number of genes regulated by diet in *Dj-1*^{-/-} mice exceeded the number in wildtype mice by 40 % and twice as many genes were regulated by genotype within the HF group compared to the control group (Fig. 3-33)¹². This indicates that the *Dj-1* deficiency combined with a HF diet causes greater adaptation on gene expression level compared to the isolated effects of *Dj-1* deficiency or HF diet-feeding. Still, interesting candidates detected by transcriptome analyses need to be validated for biological relevance in further experiments examining their protein content and activity level.

Additionally, we used the extended candidate list to conduct a pathway analysis focusing on associated disease pathways. Regarding pathways linked to metabolic diseases, several were associated with the genes regulated by diet independent of genotype including 'Hyperglycemia' and 'Diabetes Mellitus' (Fig. 3-34 A). This is remarkable considering that the diet regulated genes did not overlap between wildtype and *Dj-1*^{-/-} mice except for *Etv6*. Furthermore, genes of the pathway 'Inflammation' were overrepresented in diet-regulated genes of wildtype as well as *Dj-1*^{-/-} mice. This phenomenon is in line with current knowledge stating that inflammatory processes occur within the hypothalamus under HF diet consumption and obesity (Chapter 1.2.2) [De Souza et al. 2005; Posey et al. 2009; Wisse & Schwartz 2009; Thaler et al. 2010; Thaler et al. 2012]. On the other hand, several pathways linked to the diet-regulated genes were dependent on genotype. Interestingly, the pathways 'Obesity/Overweight/Overnutrition' and 'Body weight' were only associated with diet regulated genes in the absence of *Dj-1*. Moreover, genotype-regulated genes were associated with metabolic disease pathways only under HF diet-feeding. It has to be pointed out that differentially regulated genes linked to certain disease pathways do not necessarily imply the presence of this disease as they might also refer to protective mechanisms depending on the direction of regulation. We rather conclude that more mechanisms counter-regulating obesity might occur in *Dj-1*^{-/-} mice. As mentioned above, diet-induced gene regulation might be more pronounced in earlier phases during the feeding period. Thus, this finding indicates that regulatory mechanisms need longer to settle on a higher state of

¹² Excluding genes on chromosome 4, the number of genotype-regulated genes within the HF diet group still exceeded the number in the control group.

adiposity in *Dj-1*^{-/-} mice compared to wildtype mice and reflects the transiently increased adipose tissue.

Several compensatory mechanisms in *Dj-1* deficient mice have previously been described including the upregulation of antioxidant enzymes [Andres-Mateos *et al.* 2007] and increased mitochondrial complex activities [Pham *et al.* 2010]. This is not due to an increased number of mitochondria since we show that the content of mitochondria is similar between *Dj-1* deficient and wildtype mice in brain, skeletal muscle and white adipose tissue under unchallenged conditions. Interestingly, the pathway 'Mitochondrial Diseases' was associated with the diet-regulated genes in *Dj-1*^{-/-} mice. Based on this finding, we speculate that HF feeding has a greater impact on mitochondrial function in the absence of *Dj-1*^{-/-} and that mitochondria play an important role in the adaptation to the metabolic changes induced by HF feeding. Follow-up experiments are needed to substantiate this hypothesis.

Most importantly, several of the regulated genes were associated with pathways linked to neurodegenerative diseases or behavior. Pathways of this category were associated with diet-regulated genes only in wildtype mice implying that HF feeding affects genes that play a role in cognitive function. A negative association of obesity and cognition was suggested in a body of literature (see Chapter 1.3). No pathways related to neurodegeneration or behavior were linked to diet-regulated genes in *Dj-1*^{-/-} mice. Probably, unchallenged *Dj-1*^{-/-} mice already exhibit a gene regulation in the same direction. Regarding genotype-regulated genes, the number of associated pathways was indeed much higher in mice fed a HF diet. Remarkably, genes of the pathways 'Parkinson Disease' and 'Parkinsonian Disorders' were only overrepresented when *Dj-1*^{-/-} and wildtype mice were compared under HF conditions. Since unchallenged *Dj-1* deficient mice do not show a typical Parkinson phenotype, additional cues or challenges like feeding a HF diet are probably needed to trigger neurodegenerative pathologies in this mouse model. Therefore, we propose that behavioral tests are carried out under HF diet challenge in order to detect deficits related to PD in this *Dj-1* deficient mouse line.

Taken together, we observed that the HF diet triggered a more complex gene regulation pattern in the hypothalamus of *Dj-1*^{-/-} mice, suggesting that *Dj-1* is important for mechanisms of HF diet-induced adaptation while in its absence there is a higher need for counter-regulatory mechanisms. Having shown that with prolonged HF feeding the effect of increased body fat accumulation is a transient phenomenon, homeostatic pathways in *Dj-1* deficient mice might need longer to settle on a higher level of defended body mass.

In summary, the susceptibility of *Dj-1*^{-/-} mice to DIO is similar to wildtype mice with regard to body mass development but HF diet-feeding resulted in higher fat accumulation in *Dj-1*^{-/-} mice at the expense of lean mass. This effect was present in both sexes. Because the diet-induced obese phenotype was less pronounced in females, we concentrated on male mice investigating possible mechanisms underlying this phenotype. The changes in body composition could not be explained by measurable alterations in energy intake or expenditure while locomotor activity was generally lower in *Dj-1*^{-/-} mice. Our data imply that *Dj-1* deficiency and HF feeding interact to influence glucose levels and hypothalamic STAT3 phosphorylation without affecting glucose tolerance or anorectic leptin action. Transcriptome analyses of the ventral hypothalamus showed that HF diet-feeding triggers a more complex gene regulation pattern in the absence of *Dj-1*. From these findings, we speculate that DJ-1 exerts a stabilizing function under HF diet challenge and mice cope less efficient with the metabolic changes induced by a HF diet challenge in the absence of *Dj-1*. We earlier concluded that DJ-1 contributes to the maintenance of normal cellular homeostasis (Fig. 4-3 A). DJ-1 senses cellular changes induced by HF diet-feeding and relays this information on to signaling pathways by means of protein modification resulting in the adaptation of homeostasis (Fig. 4-3 B). Thus, in the absence of DJ-1, normal homeostasis needs to be sustained through other mechanisms which compensate the lacking DJ-1 action (Fig. 4-4 A) and prevent a stronger phenotype. When *Dj-1* deficient mice are challenged with a HF diet, these or other compensatory mechanisms need to be upregulated to enable a homeostatic adaptation (Fig. 4-4 B).

Fig. 4-4. Proposed mechanism of metabolic adaptation to nutrient abundance in the absence of DJ-1. (A) DJ-1 contributes to the maintenance of normal cellular homeostasis. Without DJ-1, normal homeostasis is sustained through other mechanisms compensating the lacking DJ-1 action. (B) Upon HF diet-feeding, compensatory mechanisms are upregulated to enable the homeostatic adaptation in the absence of DJ-1.

Most importantly, the altered body composition constitutes a transient effect depending on length of feeding and/or age. Compensational mechanisms are eventually able to counter-balance the accelerated HF diet-induced changes to the level of DIO wildtype mice. Conclusively, in the absence of *Dj-1* it might simply take longer to reach a new steady state of energy balance regulation under HF challenge.

Finally, our study supports a possible convergence or interaction of molecular pathways involved in obesity and neurodegeneration. As mentioned in the introduction, the threshold for developing age-related neurodegenerative diseases may be lowered by obesity-associated metabolic changes (Chapter 1.3). In the future, more experimental studies are needed to investigate the extent to which metabolic derangements affect mental health to eventually answer the question of how important fighting obesity and related disorders is for the prevention of neurodegenerative diseases in humans.

6 SUPPLEMENTARY DATA

6.1 Supplementary figures

Fig. S1. Comparison of DJ-1 pI isoforms in the epididymal white adipose tissue of male C57BL/6N mice after 10 days of HF or control diet. (A) Protein extracts were separated via IEF. Gels were transferred to a membrane followed by immunodetection of DJ-1. **(B)** Densitometric quantification of the signal intensities of individual DJ-1 spots ($n = 6$). Data was generated by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

Fig. S2. Comparison of DJ-1 pI isoforms in peripheral tissues of C57BL/6N mice maintained on a HF or control diet for 10 days. Protein extracts were analyzed using an automated capillary IEF immunoassay (NanoPro™ 1000, ProteinSimple). Electropherograms show the pI distribution of DJ-1 isoforms detected via chemifluorescence. Samples were measured in duplicates. Each peak likely corresponds to one DJ-1 isoform. $n_{gastrocnemius\ muscle} = 5-6$, $n_{pancreas} = 5$, $n_{liver} = 6$, $n_{epididymal\ WAT} = 3$. eWAT – epididymal white adipose tissue. Gastroc. muscle – gastrocnemius muscle. Data was generated by Dr. Daniela Besong Agbo and Dr. Hans Klafki, LVR-Klinikum Essen, Germany.

Fig. S3. Histograms of litter sizes of male and female $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice employed in the HF diet challenge. Mice derived from heterozygous breeding pairs.

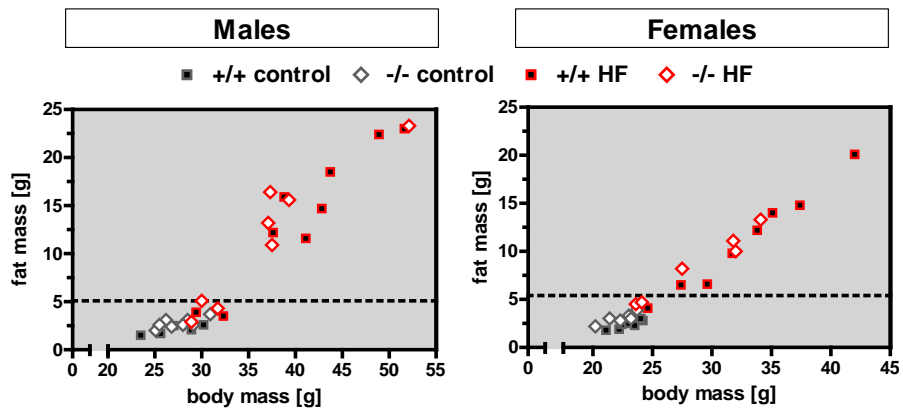

Fig. S4. Fat mass related to body mass in male and female $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice after 32 weeks of HF or control diet. The dotted line designates twice the mean fat mass of control diet-fed mice. HF diet-fed mice whose fat mass did not exceed this value were defined as non-responders.

Fig. S5. Fat mass related to body mass in male $Dj-1^{-/-}$ and $Dj-1^{+/+}$ mice maintained on HF or control diet. Mice were assigned to the diets at 4 weeks of age. Body mass and body composition were determined every two weeks.

Fig. S6. Lean mass related to body mass in male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on HF or control diet. Mice were assigned to the diets at 4 weeks of age. Body mass and body composition were determined every two weeks.

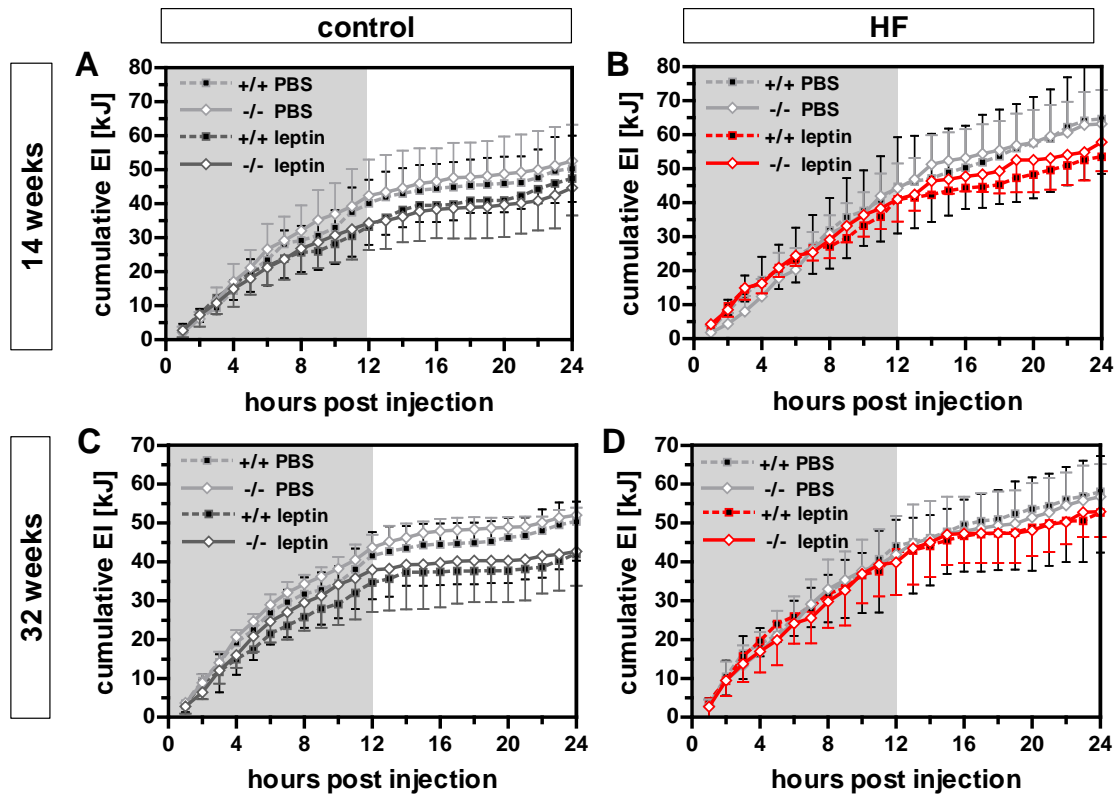

Fig. S7. Cumulative energy intake (EI) after i.p. leptin injection compared to PBS injection of male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on HF or control diet for 14 or 32 weeks. Mice received an i.p. PBS injection on three consecutive days followed by 5 mg*kg⁻¹ leptin the day after. Injections were given shortly before the onset of the dark phase. Energy intake was recorded automatically for 24 hours. EI after PBS injection represents the mean of 3 days. Grey areas indicate dark-phases. Values are means \pm SD ($n_{control}$ = 6-8, n_{HF} = 4-6).

Fig. S8. 12-hour energy intake (EI) after i.p. leptin injection of male *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on HF or control diet for 14 or 32 weeks. EI after leptin injection is expressed in percent of the EI after PBS injections (average of 3 days). Data points represent individual animals. Dashed boxes designate mice resistant to DIO. $n_{control}$ = 6-8, n_{HF} = 4-6.

Fig. S9. Gain of body mass, fat and lean mass in male C57BL/6N mice maintained on a high-fat, 'cafeteria' or control diet for 18 weeks. Mice were placed on the diets at 10 weeks of age. Animals on 'cafeteria' diet could choose from three different tasting pellets ('salt', 'biscuit' and 'chocolate'). Diets were obtained from Ssniff Spezialdiäten GmbH, Soest, Germany (control #E15000; 60 % HF #E15741-347, beef-tallow + soybean oil; Cafeteria #S0372-E022/24/26). Body composition was assessed via NMR spectrometry (Minispec; Bruker). Values are means \pm SEM (n = 10-12). General linearized model: ^{a,b}From day 93 on, all groups were significantly different from each other. *p < 0.05 HF vs. control. The experiment was performed at the German Mouse Clinic, Munich, Germany by Dr. Jan Rozman and Monja Willershäuser.

*Normalized to *Hsp90* expression. Values are means ± SD.

Table S3. Body mass, fat and lean mass of male and female *Dj-1^{-/-}* and *Dj-1^{+/+}* mice at 4 weeks of age.

	Males		Females	
	+/ n = 32	-/ n = 33	+/ n = 30	-/ n = 27
body mass [g]	14.2 ± 2.7	14.1 ± 2.4	13.0 ± 1.8	12.2 ± 1.9
fat mass [g]	1.8 ± 0.4	2.0 ± 0.4	1.8 ± 0.3	1.9 ± 0.5
lean mass [g]	10.7 ± 2.1	10.5 ± 1.9	9.6 ± 1.3	8.8 ± 1.2*

Values are means ± SD. Student's t-test *p < 0.05.

Table S4. Spontaneous locomotor activity of male and female *Dj-1^{-/-}* and *Dj-1^{+/+}* mice maintained on control diet for 32 weeks. Animals were kept in the feeding-drinking-activity setup (TSE Systems). Activity parameters of one dark-phase were analyzed after mice had been accustomed to the cages for one day. Total activity refers to beam break counts in X, Y and Z direction, horizontal activity to X and Y direction and rearing activity to Z direction (vertical movement).

	+/ n = 32	-/ n = 33	t-test p-value
Males			
total activity [counts x10³]	63.0 ± 16.8	47.5 ± 10.4	0.0484
horizontal activity [counts x10³]	59.5 ± 15.4	45.1 ± 9.9	0.0482
rearing activity [counts x10³]	3.5 ± 1.5	2.4 ± 0.6	0.0791
ambulatory movement [counts x10³]	41.9 ± 12.9	30.1 ± 8.3	0.0525
fine movement [counts x10³]	17.6 ± 2.8	15.0 ± 2.0	0.0587
distance [m]	721 ± 193	530 ± 166	0.0600
speed [m*h⁻¹]	59.0 ± 16.3	43.1 ± 14.0	0.0626
Females			
total activity [counts x10³]	83.1 ± 35.4	60.8 ± 32.1	0.3057
horizontal activity [counts x10³]	77.9 ± 33.3	57.9 ± 31.3	0.3337
rearing activity [counts x10³]	5.2 ± 2.5	3.0 ± 1.4	0.1008
ambulatory movement [counts x10³]	58.0 ± 26.8	41.0 ± 25.7	0.3156
fine movement [counts x10³]	20.0 ± 6.5	16.8 ± 5.7	0.4258
distance [m]	1031 ± 493	733 ± 420	0.3143
speed [m*h⁻¹]	85.2 ± 41.2	60.1 ± 35.4	0.3138

Values are means ± SD (n_{males} = 7-8, n_{females} = 5-6).

Table S5. Genes located on chromosome 4 found differentially regulated between *Dj-1*^{-/-} and *Dj-1*^{+/+} mice on control as well as on HF diet. Listed are representative transcripts corresponding to these genes sorted by their distance to *Dj-1* (*Park7*).

*in *Dj-1*^{-/-} versus *Dj-1*^{+/+} mice

Table S6. Diet-regulated genes in wildtype mice. Mice were maintained on HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$). A log₂ fold change > 0.26 indicates upregulation and < -0.26 downregulation in HF versus control diet-fed mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively.

*mean of log₂ fold changes of all transcripts found differentially expressed for each gene

Table S7. Diet-regulated genes in *Dj-1*^{-/-} mice. Mice were maintained on HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$). A log₂ fold change > 0.26 indicates upregulation and < -0.26 downregulation in HF versus control diet-fed mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively.

*mean of log₂ fold changes of all transcripts found differentially expressed for each gene

Table S8. Genotype-regulated genes under control diet. *Dj-1^{-/-}* and wildtype mice were maintained on control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$). A log₂ fold change > 0.26 indicates upregulation and < -0.26 downregulation in *Dj-1^{-/-}* versus *Dj-1^{+/+}* mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively. Genes regulated by genotype under both control and HF diet are listed in Table S10.

*mean of log₂ fold changes of all transcripts found differentially expressed for each gene

Table S9. Genotype-regulated genes under HF diet. *Dj-1^{-/-}* and wildtype mice were maintained on control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$). A log₂ fold change > 0.26 indicates upregulation and < -0.26 downregulation in *Dj-1^{-/-}* versus *Dj-1^{+/+}* mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively. Genes regulated by genotype under both control and HF diet are listed in Table S10.

*mean of log2 fold changes of all transcripts found differentially expressed for each gene

Table S10. Genotype-regulated genes under control as well as HF diet. *Dj-1^{-/-}* and wildtype mice were maintained on control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Listed are genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$). A log2 fold change > 0.26 indicates upregulation and < -0.26 downregulation in *Dj-1^{-/-}* versus *Dj-1^{+/+}* mice, corresponding to a fold change of > 1.2 or < -1.2 , respectively.

*mean of log2 fold changes of all transcripts found differentially expressed for each gene. Chr – Chromosome.

Table S11. Metabolic disease pathways associated with diet-regulated genes. *Dj-1^{-/-}* and wildtype mice were maintained on HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$) with a log2 fold change > 0.26 (upregulation) or < -0.26 (downregulation) in HF versus control diet-fed mice were subjected to a pathway analysis. Listed are pathways for which the number of differentially expressed genes between HF or control diet-fed wildtype (A) or *Dj-1^{-/-}* mice (B) exceeded the statistically expected number. Genes shown in bold represent overlapping genes of pathways associated with the diet-regulated genes of both genotype groups.

*number of differentially expressed genes found in the respective pathway

**total number of genes in the respective pathway

Table S12. Metabolic disease pathways associated with genotype-regulated genes. *Dj-1^{-/-}* and wildtype mice were maintained on HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Genes for which at least one transcript was found differentially expressed (Student's t-test, $p < 0.01$) with a log2 fold change > 0.26 (upregulation) or < -0.26 (downregulation) in *Dj-1^{-/-}* versus wildtype mice were subjected to a pathway analysis. Listed are pathways for which the number of differentially expressed genes between *Dj-1^{-/-}* or wildtype mice fed a control (A) or HF diet (B) exceeded the statistically expected number.

(B) Diet effect within *Dj-1^{-/-}* mice

-

*number of differentially expressed genes found in the respective pathway

**total number of genes in the respective pathway

Table S14. Pathways related to neurodegeneration or behavior associated with genotype-regulated genes. *Dj-1*^{-/-} and wildtype mice were maintained on HF or control diet for 14 weeks. The ventral hypothalamus was subjected to RNA sequencing. Genes for which at least one transcript was found differentially expressed (Student's t-test, p < 0.01) with a log2 fold change > 0.26 (upregulation) or < -0.26 (downregulation) in *Dj-1*^{-/-} versus wildtype mice were subjected to a pathway analysis. Listed are pathways for which the number of differentially expressed genes between *Dj-1*^{-/-} or wildtype mice fed a control (A) or HF diet (B) exceeded the statistically expected number. Genes shown in bold represent overlapping genes of pathways associated with the genotype-regulated genes of both diet groups.

Table S15. Proteins immunoprecipitated from mouse brain lysate using an anti DJ-1 antibody. DJ-1 was found in the precipitates of wildtype samples with a total sequence coverage of 97.9 % and high corresponding ion-intensities. Presented co-precipitated proteins have been identified and quantified in at least 15 of 18 analysed immunoprecipitates of C57BL/6N mice fed a HF or control diet for 10 days (n = 8) but not in DJ-1 deficient mice and therefore represent potential direct or indirect DJ-1 binding partner proteins. The score for protein identification (posterior error probability, PEP) was $< 5.8 \cdot 10^{-8}$. Data was generated by Dr. Gereon Poschmann, MPL, Düsseldorf, Germany.

MW – Molecular weight.

Table S16. Alterations in the hypothalamic proteome after 18 weeks of HF or 'cafeteria' feeding. Male C57BL/6N mice were either fed a 60 % high-fat (HF), 'cafeteria' or control diet (n = 6). Animals on 'cafeteria' diet could choose from three different tasting pellets ('salt', 'biscuit' and 'chocolate'). After 18 weeks on diet, hypothalami were collected and subjected to two-dimensional difference gel electrophoresis (2D-DIGE). HF or cafeteria diet-fed mice were compared to control diet-fed mice, respectively. Listed are spots with significantly differential volumes that were identified by nano-LC-ESI mass spectrometry. See Supplementary Fig. S9 for body mass and body composition data of mice and information on diets.

Protein name	Gene Symbol	UniProtK B accession no.	Average Ratio*		T-Test p-value		ANOVA + Tukey-Test p-value	
			HF/control	cafeteria/control	HF/control	cafeteria/control	HF/control	cafeteria/control

APPENDIX

I Material

I.I Diets

Fig A1. Composition of diets used in this thesis. The custom-made purified diets were obtained from Ssniff Spezialdiäten GmbH, Soest, Germany: (A) Control #S5745-E702, (B) HF #S5745-E712 (C) HF/HS #S5745-E713). Macronutrients are given in percent by weight. The amount of fat corresponds to 12 cal% for the control diet and 48 cal% for the HF or HF/HS diet.

I.II Antibodies

Table A1. List of primary antibodies.

Target protein	Host	MW [kDa]	Dilution factor	Company	Product code
Actin	mouse	43	10 000	Millipore	MAB1501
Anti-Porin (VDAC)	rabbit	~31	1000	Calbiochem	PC548T
Calnexin	goat	90	1000	Santa Cruz Biotechnology	sc-6465
COXIV	rabbit	17	5000	Cell Signaling	4844
DJ-1	rabbit	23	10 000	Biomol (Epitomics)	2398-1
Histone H3	goat	15	1000	Santa Cruz Biotechnology	sc-8654
OXPPOS Rodent AB Cocktail	mouse		350	MitoSciences	MS604
PMP70	rabbit	70	5000	Abcam	ab3421
phospho-STAT3 (Tyr705)	rabbit	80	1000	Cell Signaling	#9145
STAT3	mouse	80	1000	Cell Signaling	#9139
SOD2	mouse	25	10 000	Abcam	ab16956
Tubulin alpha	mouse	50	7500	Acris	BM753S

MW – Molecular weight. COXIV - cytochrome c oxidase subunit 4. OXPPOS - oxidative phosphorylation. PMP70 - peroxisomal membrane protein 70. SOD2 - superoxide dismutase 2. STAT3 - signal transducer and activator of transcription 3. VDAC - voltage-dependent anion channel.

Secondary antibodies were IRDye 800CW or 680 RD conjugated and obtained from LI-COR® Biosciences, Lincoln, NE, USA (#926-322 11/12/14/21/22).

I.IV Chemicals, materials, equipment, software

Chemicals, materials, and equipment were obtained from the companies Carl Roth (Karlsruhe, Germany), Sigma-Aldrich (St. Louis, MO, USA), Eppendorf (Hamburg, Germany) or Sarstedt (Nümbrecht, Germany) unless otherwise stated. Chemicals had at least p.a. quality.

Table A3. Chemicals and enzymes.

Name	Product code	Company
ADP	A2754	Sigma-Aldrich, St.Louis, MO, USA
Agarose	114046	Serva, Heidelberg, Germany
Albumin Fraction V, ≥ 98%	8076	Carl Roth, Karlsruhe, Germany
Albumin from bovin serum (for isolation of mitochondria)	A3803	Sigma-Aldrich, St.Louis, MO, USA
Amplex [®] Red	A12222	Invitrogen, Darmstadt, Germany
Antimycin A	A8674	Sigma-Aldrich, St.Louis, MO, USA
Bromphenol blue	A512	Carl Roth, Karlsruhe, Germany
CHAPS	1479	Carl Roth, Karlsruhe, Germany
1,4-Dithiothreitol	6908	Carl Roth, Karlsruhe, Germany
DMSO	4720	Carl Roth, Karlsruhe, Germany
DNA-Ladder 100 bp	T833	Carl Roth, Karlsruhe, Germany
Ethidium bromide solution 1 %	2218	Carl Roth, Karlsruhe, Germany
FCCP	C2920	Sigma-Aldrich, St.Louis, MO, USA
Formaldehyde 37 %	4979	Carl Roth, Karlsruhe, Germany

I.V Nano-HPLC-ESI tandem mass spectrometry – Material and settings

Online reversed-phase capillary HPLC:

- UltiMate 3000 HPLC system (Dionex/Thermo Scientific, Idstein, Germany)
- Acclaim PepMap100 column (3 μm C18 particle size, 75 μm inner diameter, 25 cm length) (Dionex /Thermo Scientific, Idstein, Germany)

ESI-tandem mass spectrometry analyses:

- HCT plus ion trap instrument (Bruker Daltonics, Bremen, Germany)
- nanoelectrospray ion source (Bruker Daltonics, Bremen, Germany)
- distal coated SilicaTips (FS360–20–10-D) (New Objective, Woburn, MA, USA)

General mass spectrometric parameters:

- capillary voltage: 1400 V
- end plate offset: 500 V
- dry gas: 8 l/min
- dry temperature: 160°C
- aimed ion charge control (ICC): 150 000
- maximal fill-time: 500 ms

Low-energy collision-induced dissociation (CID):

- fragmentation amplitude: 0.6 V
- MS spectra: sum of seven individual scans from m/z 300-1500; scan rate 8,100 (m/z)/s
- MS/MS spectra: sum of four scans from m/z 100-2200; scan rate 26 000 (m/z)/s

Search parameters for peptide and protein identification:

- Peptide charge states: 2⁺, 3⁺ and 4⁺
- tryptic specificity allowing one missed cleavage
- No fixed modification, oxidation of methionine as variable modification
- Ion trap MS/MS spectra cut off score: 30
- mass tolerance: 0.4 Da and 0.4 Da for MS and MS/MS experiments
- Protein identification: minimum of 2 identified peptides

Software

- Compass 1.3 for esquire/HCT Build 581.4, esquireControl version 6.2 build 62.25 (Bruker Daltonics, Bremen, Germany)
- Software tool Data Analysis (version 4 SP4 build 281) (Bruker Daltonics, Bremen, Germany)

ACKNOWLEDGEMENTS

Ich möchte mich herzlich bei allen bedanken, die zum Gelingen dieser Arbeit beigetragen haben.

Mein Dank gilt zunächst Martin. Ohne dein Mitwirken und deine Bemühungen im Rahmen des NGFN-Netzes wäre dieses Thema nicht zu Stande gekommen. Ich danke dir für deine konstruktiven Denkanstöße und Diskussionen und dafür, dass du unseren Trupp so gut managst und zusammenhältst.

Allen Mitarbeitern der Arbeitsgruppe sei für ihre Unterstützung und für die Schaffung eines so tollen Arbeitsklimas gedankt. Insbesondere danke ich Nadine für ihre unermüdliche Hilfsbereitschaft, Tobias für seine Geduld, Dinge wiederholt zu erklären und die hilfreichen Ratschläge, die er für jedwede technischen und theoretischen Probleme bereit hält, sowie Jan für seine Statistiktipp. Sabine und Anika danke ich für ihre praktischen Ratschläge und die technische Unterstützung.

Ganz besonders bedanken möchte ich mich bei Dr. Gereon Poschmann für sein unerschütterliches Engagement für dieses Projekt und sein stets offenes Ohr für fachliche Fragen. Deine wertvollen Vor- und Ratschläge sowie dein Eifer mit dem du ständig neue Ideen zutage förderst, haben wesentlich zum Gelingen dieses Projektes beigetragen.

Tobi, Jan, Gereon, Flo, Monja, Nadine und Sabine – ein riesiges Dankeschön für eure Korrekturen dieser Arbeit!

Dem Team Neurodegeneration vom Helmholtz Zentrum München unter Leitung von Prof. Dr. Wurst danke ich, dass sie uns die *Dj-1* genetrap Mauslinie für die Zucht zur Verfügung gestellt haben. Ein großer Dank geht hierbei an Dr. Andreas Hofmann für die fachlichen Diskussionen per E-Mail sowie Dr. Daniela Vogt-Weisenhorn für ihre Anregungen und die Gespräche.

Dr. Karol Szafranski und Dr. Marco Groth vom Fritz-Lipmann-Institut, Jena, danke ich für die RNA Sequenzierung und die fachliche Unterstützung bei der Bewältigung der Datenflut.

Prof. Dr. Skerra und seinen Mitarbeitern danke ich für die Bereitstellung des Leptins.

Frau Prof. Dr. Schnieke und Herrn Prof. Dr. Haller danke ich, dass sie die Mühen als Zweitgutachterin bzw. als Vorsitzender der Prüfungskommission auf sich genommen haben.

Nicht zuletzt danke ich meinen Eltern für ihre Unterstützung und ihr fortwährendes Vertrauen darin, „dass ich das schon schaffen werde“.

Diese Arbeit wurde durch NGFN-Plus gefördert (01GS0822).

EIDESSTATTLICHE ERKLÄRUNG

Ich erkläre an Eides statt, dass ich die bei der Fakultät Wissenschaftszentrum Weihenstephan für Ernährung, Landnutzung und Umwelt (promotionsführende Einrichtung) der TUM zur Promotionsprüfung vorgelegte Arbeit mit dem Titel

The Role of the Parkinson's Disease associated Protein DJ-1 in the
Development of Diet-induced Obesity in Mice

am Lehrstuhl für Molekulare Ernährungsmedizin unter der Anleitung und Betreuung durch Prof. Dr. Martin Klingenspor ohne sonstige Hilfe erstellt und bei der Abfassung nur die gemäß § 6 Abs. 6 und 7 Satz 2 angegebenen Hilfsmittel benutzt habe.

Ich habe keine Organisation eingeschaltet, die gegen Entgelt Betreuerinnen und Betreuer für die Anfertigung von Dissertationen sucht, oder die mir obliegenden Pflichten hinsichtlich der Prüfungsleistungen für mich ganz oder teilweise erledigt.

Ich habe die Dissertation in dieser oder ähnlicher Form in keinem anderen Prüfungsverfahren als Prüfungsleistung vorgelegt.

Ich habe den angestrebten Doktorgrad noch nicht erworben und bin nicht in einem früheren Promotionsverfahren für den angestrebten Doktorgrad endgültig gescheitert.

Die öffentlich zugängliche Promotionsordnung der TUM ist mir bekannt, insbesondere habe ich die Bedeutung von § 28 (Nichtigkeit der Promotion) und § 29 (Entzug des Doktorgrades) zur Kenntnis genommen. Ich bin mir der Konsequenzen einer falschen Eidesstattlichen Erklärung bewusst.

CURRICULUM VITAE

PROMOTION & STUDIUM

- seit Dez. 2008* **Promotion an der Technischen Universität München**
Lehrstuhl für Molekulare Ernährungsmedizin
- Okt. 2003 –
Okt. 2008* **Studium der Ernährungswissenschaften Friedrich-Schiller-Universität Jena**
- Diplomarbeit am Deutschen Institut für Ernährungsforschung Potsdam-Rehbrücke, Abteilung Ernährungstoxikologie
Thema: „Massenspektrometrische, genetische und kinetische Charakterisierung zweier Formen der murinen Sulfotransferase 1A1“
 - *Abschluss:* Diplom (Note 1,1)
 - Diplomarbeitspreis des APFEL e.V. Friedrich-Schiller-Universität Jena

SCHULBILDUNG

- 1993 – 2002* **Friederiken-Gymnasium Bernburg**
- *Abschluss:* Abitur (Note 1,2)
 - Karl-von-Frisch-Abiturienten-Preis für hervorragende Leistungen im Fach Biologie
- 1991 - 1993* **Grundschule Karlstraße, Bernburg**
- 1989 – 1991* **Polytechnische Oberschule Karl-Liebknecht, Bernburg**

PRAKTIKA & NEBENTÄTIGKEITEN

- *Feb. 2008 –
Sep. 2008* **Deutsches Institut für Ernährungsforschung Potsdam-Rehbrücke** Studentische Hilfskraft
- *März 2007* **Thüringer Landesanstalt für Landwirtschaft, Jena** Praktikum beim Thüringer Agrarmarketing („Regionale Speisekarte“)
- *Aug. 2006* **Friedrich-Schiller-Universität Jena** Forschungspraktikum am Lehrstuhl für Ernährungstoxikologie
- *März/April 2006* **Anhaltinische Pflanzen-zucht GmbH, Bernburg** Praktikum in der Maisforschung
- *Okt. 2005 –
Jan. 2006* **Friedrich-Schiller-Universität Jena** Studentische Hilfskraft
- *Aug./Sep. 2005* **Leibnitz-Institut für Naturstoffforschung, Jena** Praktikum in der Nachwuchsgruppe „Pathogene Pilze“

TAGUNGSGANG, KONFERENZEN UND WEITERBILDUNGEN

- *Dez 2012* 5th Annual Meeting of NGFN-Plus and NGFN-Transfer, Heidelberg Posterbeitrag
- *Mai 2012* 19th European Congress on Obesity (ECO2012), Lyon, France Posterbeitrag
- *März 2012* 49. wissenschaftlicher Kongress der Deutschen Gesellschaft für Ernährung e.V., Freising Präsentation
- *Okt. 2011* Sattelintensivsymposium "From Causes of Obesity to Clinical Applications", Essen
- *Okt. 2011* 27. Jahrestagung der Deutschen Adipositas-Gesellschaft, Bochum Posterbeitrag
- *Nov. 2010* 3rd Annual Meeting of NGFN- Plus and NGFN-Transfer, Berlin Posterbeitrag
- *Nov. 2009* 2nd Annual Meeting of NGFN- Plus and NGFN-Transfer, Berlin Posterbeitrag
- *Nov. 2009* Kompaktkurs „Versuchstiere, Tierversuche und Ersatzmethoden“, Berlin Zertifikat nach FELASA Kat. B
- *Juni 2009* 16. Arbeitstagung: Mikromethoden in der Proteinbiochemie, München
- *Mai 2009* Neurizons, Göttingen Posterbeitrag
- *Feb./März 2009* Erasmus Intensive Course "Combating Obesity – Strategies for Prevention and Intervention (COSPI)", Grundlsee, Österreich Präsentation
- *Dez. 2008* 1st Annual Meeting of NGFN- Plus and NGFN-Transfer, München
- *Sept. 2008* NuGO week 2008, Potsdam
- *Feb. 2008* DIfE Symposium "Genetics and Pathophysiology of Type 2 Diabetes", Potsdam

PUBLIKATIONEN

Besong Agbo D, Klafki HW, Poschmann G, Seyfarth K, Genius J, Stühler K, Wurst W, Meyer HE, Klingenspor M, Wiltfang J (2013). Development of a Capillary Isoelectric Focusing Immunoassay to Measure DJ-1 Isoforms in Biological Samples. *Analytical Biochemistry*. 443(2):197-204

SONSTIGES

Auslandsaufenthalt Neuseeland - *Aug. 2002 – Aug. 2003*

Persönliche Angaben

- *Geburtsdatum:* 27.09.1982
- *Geburtsort:* Bernburg
