

## **Characterization of T-cell receptors for clinical translation**

Stefan Audehm

Vollständiger Abdruck der von der Fakultät für Medizin der Technischen Universität München zur Erlangung des akademischen Grades eines Doktors der Naturwissenschaften (Dr. rer. nat.) genehmigten Dissertation.

Vorsitzender: Prof. Dr. Dirk Busch

Prüfende der Dissertation:

1. Prof. Dr. Angela Krackhardt
2. Prof. Dr. Aphrodite Kapurniotu

Die Dissertation wurde am 25.09.2019 bei der Technischen Universität München eingereicht und durch die Fakultät für Medizin am 10.03.2020 angenommen.

## Summary

Among the immunotherapies, the adoptive T-cell transfer with immunoreceptor transgenic T cells has demonstrated high efficacy in tumor diseases. This becomes clear primarily through the use of chimeric antigen receptors (CAR) used to target B cell-derived tumors. While there are only a small number of different CARs available, due to the lack of suitable target structures on various tumor cells, classic T-cell receptor (TCR) therapies have a great advantage. The working principle of TCR recognition of endogenously processed peptides derived from cellular proteins presented to the immune system by cell-surface major histocompatibility complexes (MHCs), allows a much higher number of potentially available TCRs compared to CARs. However, one of the biggest challenges is finding a TCR that is both highly effective and safe to use. To achieve this, both the TCRs and the corresponding target peptides on the MHCs have been assigned to a variety of characteristics, that might allow selecting TCRs potentially suitable for clinical translation. Since most of these characteristics were identified in the autologous system, this work aims to evaluate them by the most common and sophisticated methods applied for the allogeneic system. In order to propose a set of relevant and time-efficient preclinical methods to select for the most suitable allogeneic receptors, two TCRs recognizing different peptides derived from the differentiation antigen myeloperoxidase (MPO) with the same MHC restriction were compared to each other. Special attention was laid on surface expression, functional avidity, cytokine secretion, cytotoxicity, and TCR-peptide-MHC dissociation rates. Furthermore, the restricted peptide-MHC complexes (p-MHC) were examined in-vitro by stability experiments such as UV-mediated peptide exchange, differential fluorometry and by mass spectrometry. Finally, the p-MHC complexes were studied using sequence- and structure-based in-silico analyses. In summary, TCR-trans-

genic T cells showed considerable differences in their anti-tumor efficacy in mouse experiments which was not predictable by the displayed similar functional avidity, TCR-p-MHC dissociation rate, and cytotoxicity in-vitro. Substantial differences, however, were found in surface expression between both TCRs as well as cytokine secretion and cross-reactivity of TCR-transgenic T cells. Besides these three attributes, the p-MHC complex studies identified low peptide flexibility within the MHC binding pocket and high p-MHC affinity as the most important criteria for the selection of p-MHC combinations with the potential of clinical utility.

## Zusammenfassung

Unter den Immuntherapien hat der adoptive T-Zelltransfer mit Immunrezeptor-transgenen T-Zellen bei Tumorerkrankungen eine hohe Wirksamkeit bewiesen. Dies ist vor allem durch den Einsatz von Chimären Antigen Rezeptoren (CAR) gegen B-Zell abgeleitete Tumorerkrankungen deutlich geworden. Während es hier, aufgrund fehlender geeigneter Zielstrukturen auf den Tumorzellen, nur eine geringe Zahl wirksamer CARs zur Bekämpfung von unterschiedlichsten Krebsarten gibt, haben klassische T-Zellrezeptoren (TCR) einen großen Vorteil. Durch ihr Funktionsprinzip, endogen prozessierte Peptide, die von zelleigenen Proteinen stammen und von Haupt-Histokompatibilitäts-Komplexen (MHC) auf der Zelloberfläche dem Immunsystem präsentiert werden, zu erkennen, ist die Anzahl potenziell möglicher TCRs im Vergleich zu den CARs um ein Vielfaches höher. Eine der größten Herausforderungen liegt jedoch darin, einen TCR zu finden, der gleichzeitig hoch wirksam und sicher in der Anwendung ist. Um dies zu erreichen, wurden sowohl den TCRs als auch den entsprechenden Zielpeptiden auf den MHCs in den letzten Jahrzehnten eine Vielzahl an Charakteristika zugewiesen, auf Basis derer ein TCR als potenziell erfolgreich für die klinische Translation eingeschätzt werden kann. Da diese Erkenntnisse überwiegend aus dem autologen System stammen, wurde in dieser Arbeit die Gültigkeit im allogenen System überprüft und ein Set geeigneter Methoden vorgeschlagen, mit deren Hilfe eine zielgerichtete und zeiteffiziente präklinische Charakterisierung von TCRs aus dem allogenen Repertoire durchgeführt werden kann. Hierzu wurden zwei TCRs ausgewählt, die unterschiedliche Peptidsequenzen aus dem Differenzierungsantigen Myeloperoxidase (MPO) mit gleicher MHC-Restriktion erkennen und zusammen mit deren Peptid-MHC Komplexe (p-MHC) sowohl in-vitro, in-vivo als auch in-silico untersucht. Besonderes Augenmerk lag dabei auf der Oberflächenexpression, funktioneller Avidität, Zytokinsekretion, Zytotoxizität und Dissoziierungsgeschwindigkeiten der TCR-Peptid-

MHC-Komplexe. Die MPO-p-MHC Komplexe wurden mittels verschiedener Stabilitäts-experimente wie UV-vermitteltem Peptid-Austausch und differenzieller Fluorometrie oder mit Hilfe der Massenspektrometrie experimentell untersucht. Abrundend wurden beide MPO-p-MHC Komplexe sowohl mit Sequenz- als auch mit Struktur-basierten in-silico Analysen charakterisiert. Zusammenfassend zeigt diese Arbeit, dass beide TCRs in Mausversuchen sehr beträchtliche Unterschiede in ihrer anti-Tumor-Effizienz zeigen und dies auf Basis nahezu identischer funktioneller Avidität, TCR-p-MHC Dissoziationsgeschwindigkeit und Zytotoxizität in-vitro nicht vorhersagbar gewesen wäre. Deutliche Unterschiede ergaben sich jedoch auf TCR-Seite in der Oberflächenexpression zwischen beiden TCRs, der Zytokinsekretion und Kreuzreaktivitätsprofil TCR-transgener T-Zellen, während sich bei den Untersuchungen der p-MHC Komplexe geringe Peptidflexibilität in der MHC-Bindungstasche bei gleichzeitiger hoher Affinität als aussagekräftige Kriterien für die Auswahl präklinisch geeigneter TCR-p-MHC Kombinationen herausstellten.

# 1 Introduction

## 2 1.1 Introduction

3 Within the last decades, adoptive cell therapies (ACT) using T cells evolved into a spe-  
4 cific and potent treatment modality for a variety of patients. Since the beginning of treat-  
5 ment with tumor infiltrating lymphocytes [1], isolated from tumor material and expanded  
6 in-vitro, a well-defined and specific T-cell product can be administered in adoptive T-cell  
7 therapies today [2]. ACT mainly refer to treatments with lymphocytes, either modified  
8 [3-5] or unmodified [6-8] and to the treatment using antigen-presenting cells to fight var-  
9 ious diseases either directly or to stimulate the recipient immune response, respectively.  
10 Thereby, ACT is often used in the background of stem cell transplantation to treat oppor-  
11 tunistic viral [9, 10] and fungal infections [11], or to treat relapses [4].

12 T-cells, intended for the use in ACT modality, can be equipped with different kind of  
13 immune receptors to enhance specificity and to engage target cells presenting well-de-  
14 fined antigens. Regarding this, mainly two types of genetically engineered immune re-  
15 ceptors are used to redirect T cells to their selected target antigen. The first type of im-  
16 mune receptors comprises chimeric antigen receptors (CAR) composed of different ex-  
17 tracellular, antigen binding domains as e.g. single-chain variable-fragments from antibod-  
18 ies [12], membrane-tethered ligands [13] or camelid single-domain antibodies [14] fused  
19 to various intracellular domains that evolved over the last years [3, 15]. CARs are de-  
20 signed to recognize extracellular epitopes expressed on the surface of the cells. So far,  
21 CARs are mainly used for B-cell malignancies and with promising outcomes [3, 16-20].

22 In contrast, the second type of immune receptor used for T-cell engineering, the alpha-  
23 beta T-cell receptor, targets intracellular processed antigens derived from whole proteins  
24 presented as peptides (p) in an MHC (major histocompatibility complexes)-dependent

25 manner [21-23]. This antigen processing and presentation is one significant advantage of  
26 TCRs, since the whole pool of translated proteins with subsequent processing and surface  
27 presentation may serve as immunogenic target. The number of possible TCR-p-MHC  
28 combinations suitable for clinical application is a lot higher compared to potential CAR-  
29 antigen combinations [24]. A second major difference is the principle of target cell recog-  
30 nition. Whereas a CAR directly binds the epitope that is presented on the surface of the  
31 target cells, the TCR-based recognition relies on three components. These comprise the  
32 peptide, the peptide-presenting MHC molecule and the TCR itself, forming a tri-molecu-  
33 lar complex to initiate the TCR-dependent immune response of T cells [25, 26]. Another  
34 advantage that becomes increasingly apparent as a critical point is the possibility to target  
35 also the tumor-promoting microenvironment via cross-presented and tumor-derived pep-  
36 tides on stroma cells by T cells [27, 28]. As a proof of clinical efficacy, TCR-engineered  
37 T cells were applied successfully in a number of clinical settings [29-33].

38 Concurrently, the countless number of possible TCR-p-MHC combinations and the pro-  
39 teasomal processing of proteins with p-MHC presentation in nearly all eukaryotic cells  
40 holds the risk of possible crossreactivity. Target or unrelated peptides can be presented  
41 on healthy tissues and may be recognized by TCRs leading to severe crossreactivity [34-  
42 36]. One possibility to minimize the risk of on- or off-target toxicities might be the usage  
43 of TCRs directed against peptides presented on MHCs derived from tumor-specific neo-  
44 antigens [37-39].

45 However, the major challenge seems to be the choice of a target peptide with favorable  
46 characteristics which are proposed to be of fundamental importance for effective T-cell  
47 responses. Previous studies emphasize the importance of high peptide-MHC affinity [27],  
48 optimal peptide length [40], superior peptide-mediated MHC-stability [41] or simply a  
49 confirmed cell surface presentation [39, 42-45]. Optimal combinations thereof may have

50 synergistic effects for enhanced presentation levels of targeted p-MHC epitopes and  
51 therefore may lead to more potent T-cell responses.

## 52 1.2 T cells equipped with engineered immune receptors

53 Both types of immune receptors mentioned above are mainly introduced into T-lympho-  
54 cytes by either retro- or lentiviral transfer [5, 46], or applying transposon technology [47].  
55 However, new methodologies for site-directed gene transfer using the CRISPR/Cas tech-  
56 nique are available to insert the CAR- or TCR-coding sequence directly into the endoge-  
57 nous TCR-gene locus [48, 49] to disrupt endogenous TCR expression and thereby poten-  
58 tially preventing TCR mispairing and related crossreactivity. Besides safety aspects re-  
59 garding site-directed CAR- and TCR-sequence integration via CRISPR/Cas versus ran-  
60 dom genome integration using viral vectors [50], the engineered TCR expression levels  
61 also seems to be influenced by the endogenous TCR because of competition for free avail-  
62 able CD3 complexes between both TCR [51]. In some cases, the expression quality is  
63 also determined by the respective dominance potential of the introduced TCR [52].

## 64 1.3 Identification of suitable TCR for engineered T-cell therapy

### 65 1.3.1 Where antigen-specific T cells can be found

66 One approach, on which this work is based, uses mature dendritic cells from healthy do-  
67 nors electroporated with in-vitro transcribed RNA encoding for a desired allogeneic  
68 MHC. Together with external pulsing of the peptide of interest, T cells with matching  
69 TCRs are primed and stimulated for clonal expansion [43, 53]. Although this approach  
70 can be a source for the identification of high affinity and tumor-antigen specific TCRs, it  
71 is often difficult to separate specific T-cell candidates from T cells that are bearing TCRs

72 with unspecific recognition of allogeneic MHC irrespective of the peptide of interest.  
73 Searching for TCR in the autologous background can eliminate this MHC alloreactivity  
74 but often lead to only low or intermediate affinity TCRs because of intra-thymic T-cell  
75 elimination of high-affinity  $\alpha\beta$ -TCRs to avoid self-reactive T cells [54]. In general, gene  
76 therapies using autologous TCRs are very often hindered because of missing expression  
77 of common tumor-derived self-antigens [55] spread over patient cohorts. Additionally,  
78 promising TCRs including neoepitope specific TCRs have been directly identified within  
79 cancer patients [39, 56]. Murine TCRs, discovered on T cells in HLA-A2-transgenic mice  
80 that have been immunized with potential target peptides derived from p53 and tumor-  
81 associated antigen gp100, have also been used for T-cell engineering [57]. However,  
82 TCRs of murine background are potentially prone to elicit antibody- or T-cell related  
83 responses against the murine variable chains of the transgenic TCR in some patients [58].  
84 To avoid the recognition of murine transgenic TCR by the host immune system, an im-  
85 proved murine approach leading to fully human variable TCR chains was established in  
86 HLA-A\*02:01-transgenic mice carrying the human T-cell repertoire [59].

### 87 1.3.2 Immunopeptidomic approach to find peptide candidates

88 Although in-silico tools are available to predict potential T-cell epitopes from proteins  
89 [60, 61], the risk remains that the predicted peptide of interest is not presented on the  
90 surface of the target cells [62] because the proteasome composition or the protein se-  
91 quence itself may not allow processing that will result in the desired peptide sequence.  
92 Immunopeptidomics, however, directly identifies HLA-bound peptides by mass spec-  
93 trometry after elution of peptides from HLA complexes that have been precipitated out  
94 of target cell lysates [63]. Since first approaches for immune proteome characterization  
95 were available, the field was extensively improved and is nowadays even proficient to

96 directly detect neoepitopes on patients' tumor material [39, 64]. However, direct quanti-  
97 fication of peptide presentation levels on target cells remains challenging because of in-  
98 dividual side chain characteristics of amino acids. The quantification of peptide presen-  
99 tation would be beneficial for instance to determine minimal peptide presentation levels  
100 on tumor cells necessary for efficient T-cell responses. Unfortunately, methods for pep-  
101 tide and protein quantifications lacks behind the quantification of small molecules using  
102 mass spectrometry [65].

### 103 1.3.3 How suitable peptide candidates can be estimated

104 Even if immunopeptidomics is applied to ensure that peptides are indeed presented on the  
105 surface of the target cell, the list of identified peptide candidates might be very long.  
106 Therefore, a proper filter strategy is needed to consolidate the list to the most promising  
107 peptide candidates. The reduction of peptide candidates is often achieved by focusing on  
108 the most frequent HLA alleles present in the population and the length of the peptides,  
109 typically comprising eight to eleven amino acids. Following this, very often sequence-  
110 based peptide-MHC binding affinity predictions based on artificial neural networks is  
111 performed to select for peptides with the best binding characteristics [66-68] or the high-  
112 est scores calculated by specific sequence motifs [69]. Historically, even complex scoring  
113 matrices were used to predict sequence-based binding affinities [70]. However, the most  
114 sophisticated algorithms using statistic- and sequence-based algorithms [71-73] might  
115 have limitations because the quality often depends on available experimental results used  
116 to train underlying algorithms. Therefore, the prediction results might be biased by the  
117 available data set [74]. To be independent of extensive experimental data sets for algo-  
118 rithm training that are only available for those MHC-alleles that have a higher prevalence  
119 in the population, and to get more insight in peptide-MHC binding, structure-based pre-  
120 dictions are increasingly being used. Currently used approaches for p-MHC modeling and

121 structure-based binding affinity [75] are promising tools to get insights into the molecular  
122 basis of peptide binding to MHC molecules and, if combined with experimental in-vitro  
123 results in interdisciplinary approaches, to estimate immunogenicity of TCR-mediated T-  
124 cell responses.

#### 125 1.3.4 How suitable TCR candidates can be selected

126 A lot of criteria and qualities have been proposed to be crucial for TCRs to be suitable for  
127 concurrent effective and safe T-cell responses. Functional T-cell avidity and TCR affin-  
128 ity, mainly tested in co-incubation assays with titrated amounts of peptides pulsed on  
129 target cells [76, 77] and sophisticated  $k_{on}$  and  $k_{off}$  analyses of TCR-p-MHC complexes  
130 [78-81], respectively, are described to be of utmost importance [82-85]. Thereby, the bal-  
131 ance between too high or too low avidity seems to be important to induce adequate TCR-  
132 mediated T-cell responses. It was discovered that T cells with high-affinity TCRs need  
133 less peptide-MHC complexes for stimulation or proliferation [82, 86]. However, if TCR  
134 affinity exceeds a tolerable level and displays superior binding characteristics, there might  
135 be a high risk for off-target toxicity [34, 36]. In contrast, low avidity TCRs may prolif-  
136 erate well and exert cytotoxicity in-vitro but seem to be inferior in reactivity as shown for  
137 viral infections in-vivo [82, 87].

#### 138 1.3.5 How TCR mediated crossreactivity can be assessed

139 Crossreactivity is an important aspect of TCR characterization. Even if a superior target  
140 peptide with sufficient expression was found, and its presentation is limited to tumor cells,  
141 a risk of TCR-related crossreactivity can remain because of slight flexibility within the  
142 CDR-domains of the TCR [88] also known as TCR degeneracy for peptides [89] that  
143 might lead to off-target toxicity. Very often a screening of randomly chosen peptides with

144 known MHC restriction is performed to estimate the recognition of the p-MHC com-  
145 plexes by the TCR [43]. Another screening approach for highly similar peptides uses  
146 amino acid exchanges within the target peptide sequence [90]. This approach is concur-  
147 rent able to identify the TCR binding motif [43, 91] and to reveal possible crossreactivity  
148 [34-36, 92]. Evaluating whether the TCR candidate also recognizes further MHC-alleles,  
149 a library of immortalized lymphoblastoid B-cell lines with various MHC expression is  
150 frequently applied [43, 93, 94].

151

## 152 1.3 Aim of this study

153 There is a considerable gap between the promise of immunotherapies using TCR-trans-  
154 genic T cells in adoptive T-cell transfer and the time necessary to identify concurrent safe  
155 and effective TCR as well as target epitopes suitable for clinical translation. The person-  
156 alization of this therapeutic approach is high since TCR are restricted to a high diversity  
157 of human leukocyte antigens and may only target antigens relevant for one specific cancer  
158 type or even a single tumor. Many assays for epitope- and TCR-characterization have  
159 been proposed in the autologous self-restricted setting. The selection process for MHC-  
160 mismatched TCR, however, is less well defined and specific features of TCR-MHC-pep-  
161 tide interaction need to be considered. Nevertheless, especially this approach provides  
162 access to non-selected TCR repertoires with highly tumor reactive TCR. Therefore,  
163 within this work, the selection criteria for both epitope candidates and respective al-  
164 lorestricted TCR are questioned and a timely workflow for the process of development is  
165 proposed.

166

## 167 2 Materials and Methods

## 168 2.1 Materials

## 169 2.1.1 Technical equipment

170 **Table 1: Technical equipment**

Device or Unit	Manufacturer
Electrophoresis chamber	G&P Kunststofftechnik, Kassel, Germany
Electrophoresis power supply	VWR, Darmstadt, Germany
Centrifuge 5810R	Eppendorf AG, Hamburg, Germany
Centrifuge J2-HS	Beckman Coulter, Brea, USA
Centrifuge 5417R	Eppendorf AG, Hamburg, Germany
Axiovert 40C microscope	Carl Zeiss Microscopy, Oberkochen, Germany
Analytical balance SI-64	Denver Instrument, Göttingen, Germany
Analytical balance 440-35N	Denver Instrument, Göttingen, Germany
Cytometer LSRII	BD Bioscience, Franklin Lakes, USA
Laminar Flow HERAsafe	Heraeus Holding, Hanau, Germany
Irradiation Cabinet	Gulmay, Byfleet, UK
Incubator BBD6220	Heraeus Holding, Hanau, Germany
-80°C Freezer	Buchner Labortechnik, Pfaffenhofen, Germany
-20°C Freezer	Liebherr-International AG, Bulle, Switzerland
Megafuge 1.0R	DJB Labcare Ltd, Buckinghamshire, UK
Magnet stirrer	Janke & Kunkel, Staufen, Germany
Tube rotator MACSmix	Miltenyi Biotec, Bergisch Gladbach, Germany
Vortex-Genie 2	Scientific Industries, Inc., Bohemia, New York, USA
Thermomixer comfort for 1.5-2.0 ml tubes	Eppendorf AG, Hamburg, Germany
Biometra T professional gradient Thermocycler	Biometra, Göttingen, Germany
StepOnePlus Real-Time PCR System	Applied Biosystems, life technologies, Carlsbad, USA
Pipetboy/Pipetgirl INTEGRA	Biosciences, Fernwald, Germany
Neubauer Counting Chamber	Karl Hecht, Sondheim/Röhn, Germany
Acura® manual 855, multichannel micropipettes (20µl-200µl)	Socorex Isba S.A., Switzerland
NanoDrop ND-100	Peqlab Biotechnologie, Erlangen, Germany
Pipettes (0,5µl-1000µl), multichannel micropipettes (20µl-200µl)	Eppendorf AG, Hamburg, Germany
High-performance cell sorter MoFlo	Dako, Agilent Technologies, Glostrup, Denmark

Separator MidiMACS TM	Miltenyi Biotec, Bergisch Gladbach, Germany
Sunrise 96-well Microplate Reader	Tecan, Männedorf, Switzerland
Peptide synthesizer ResPepMicroScale	Intavis AG Bioanalytical instruments, Cologne, Germany
Nano-flow UHPLC EASY-nLC 1200 system	Thermo Fisher Scientific, Waltham, Massachusetts, USA
Nanoelectrospray unit	Thermo Fisher Scientific, Waltham, Massachusetts, USA
Mass spectrometer Q Exactive HF-X	Thermo Fisher Scientific, Waltham, Massachusetts, USA
UV hand lamp	Köhler Technische Produkte, Neulußheim, Germany
Digital incubators, INCU-Line®	VWR, Darmstadt, Germany
Innova 4000 Benchtop Incubator Shaker	New Brunswick Scientific, Enfield, CT, USA
Electroporation Systems Gene Pulser Xcell™ + CE module	Bio-Rad Laboratories GmbH, Munich, Germany
Cryogenic storage systems BIOSAFE®-MD	Cryotherm GmbH & Co. KG, Kirchen/Sieg, Germany
Centrifuge Avanti J-E	Beckman Coulter GmbH, Krefeld, Germany
Waterbath WNB	Memmert GmbH & Co. KG, Schwabach, Germany
Plate shaker Titramax 1000	Heidolph Instruments GmbH & CO. KG, Schwabach, Germany
Micro scales Balance summit	Denver Instrument, Göttingen, Germany

171

172 **2.1.2 Consumables**173 **Table 2: Consumables**

<b>Consumables</b>	<b>Company</b>
Pipet tips: 10µl, 100µl, 200µl, 1000µl	Sarstedt, Nümbrecht, Germany
Parafilm	Pechiney Plastic Packaging, Inc., Chicago, USA
Freezing Container, Mr. Frosty™	Nunc, Roskilde, Denmark
Gloves nitrile	KCL, Eichenzell, Germany
Gloves Latex	Sempermed, Wien, Austria
Tubes 15 ml, 50 ml	BD Bioscience, Franklin Lakes, USA
Cell culture flask	Greiner Bio-One, Frickenhausen, Germany
Inoculating loops, PS	VWR, Darmstadt, Germany
Serological pipets (2,5,10,25,50ml)	Sarstedt, Nümbrecht, Germany
Nunc-Immuno™ MicroWell™ MaxiSorp™ flat bottom plate 96 well solid plates	Nunc, Roskilde, Denmark
Filter tips: 10µl, 100µl, 200µl, 1000µl	Sarstedt, Nümbrecht, Germany
Cell separation Columns MACS LD, LS	Miltenyi Biotec, Bergisch Gladbach, Germany
Cell scraper PE 300 mm	TPP Techno Plastic Products, Trasadingen, Switzerland
Nunclon® Δ surface treatment flasks	Nunc, Roskilde, Denmark
MicroAmp™ Fast Optical 96-Well Reaction Plate with Bar- code, 0,1 mL	Thermo Fisher Scientific, Waltham, MA, USA

CryoPure tube: 1,6 ml	Sarstedt, Nümbrecht, Germany
Syringe filter: 0,22µm, 0,45µm	TPP Techno Plastic Products, Trasadingen, Switzerland
Stericup Vacuum Filter Units 0,22µm	Merck Millipore, Darmstadt, Germany
Not Treated Multiple Well Plates: 6, 24 well	BD Bioscience, Franklin Lakes, USA
Reaction tubes: 1.5µl, 2ml	Sarstedt, Nümbrecht, Germany
PCR Reaction tubes: 0.5µl	Peqlab Biotechnologie, Erlangen, Germany
Tissue culture plates, 96, 48, 24, 12, 6 well, round/flat bottom	TPP Techno Plastic products, Trasadingen, Switzerland
Cell strainer 40µm, 100µm	BD Bioscience, Franklin Lakes, USA
Syringe: 5ml, 10ml, 50ml	BD Bioscience, Franklin Lakes, USA
MaxiSorp™ flat-bottom 96 well plate	Nunc, Roskilde, Denmark
Sub_Q syringe 1 ml	BD Bioscience, Franklin Lakes, USA
Sealing Foil	Alpha laboratories, Hampshire, UK
Tubes for flow cytometry, round bottom	BD Bioscience, Franklin Lakes, USA
Petri dishes	Greiner Bio-One, Frickenhausen, Germany

174

## 175 2.1.3 Reagents

176 **Table 3: Reagents**

Reagents	Company
DNA ladder: 100bp, 1 kb	New England Biolabs, Ipswich, UK
7-Aminoactinomycine D	Merck, Darmstadt, Germany
Gel loading dye 6x	Fermentas, St.Leon-Rot, Germany
Agarose standard	Roth, Karlsruhe, Germany
AIM-V medium	Invitrogen, Carlsbad, USA
Ampicillin	Merck, Darmstadt, Germany
Bovine serum albumine (BSA)	Merck, Darmstadt, Germany
ACK lysis buffer	ThermoFisher Scientific, Waltham, USA
DEPC-H <sub>2</sub> O	Invitrogen, Carlsbad, USA
1,4 Dithiothreitol	Merck, Darmstadt, Germany
DMEM medium	Invitrogen, Carlsbad, USA
VLE-RPMI	Merck, Darmstadt, Germany
DMSO (Dimethylsulfoxide)	Merck, Darmstadt, Germany
PBS (Phosphate buffered saline)	Invitrogen, Carlsbad, USA
EDTA (Ethylenediaminetetraacetic acid)	Invitrogen, Carlsbad, USA
Ethanol	Merck, Darmstadt, Germany
Ethidium bromide	Roth, Karlsruhe, Germany

Fetal bovine serum, heat inactivated (FCS)	Invitrogen, Carlsbad, USA
Ficoll	Biochrom, Berlin, Germany
DNA ladder Gene Ruler 1 kb	PeqLab, Erlangen, Germany
Gentamicin	Merck, Darmstadt, Germany
RNase out	Invitrogen, Carlsbad, USA
Sulfuric acid (H <sub>2</sub> SO <sub>4</sub> )	Roth, Karlsruhe, Germany
HBSS (Hank's Balanced Salt Solution)	Invitrogen, Carlsbad, USA
HEPES (Hydroxyethylpiperazine ethane sulfonic acid)	Invitrogen, Carlsbad, USA
Human serum, heat inactivated (HS)	TU Munich, München, Germany
Isoflurane	CP-Pharma, Burgdorf, Germany
Penicillin	Invitrogen, Carlsbad, USA
Streptomycin	Invitrogen, Carlsbad, USA
OneShot TOP10 bacteria	Invitrogen, Carlsbad, USA
Streptavidin	Sigma Aldrich, St. Louis, USA
NEB5 $\alpha$ bacteria	New England Biolabs, Ipswich, UK
Non-essential amino-acids	Invitrogen, Carlsbad, USA
Sodium azide	Merck, Darmstadt, Germany
Sodium chloride	Merck, Darmstadt, Germany
Mycophenolic acid	Merck, Darmstadt, Germany
L-Glutamine	Invitrogen, Carlsbad, USA
LB Broth Base	Invitrogen, Carlsbad, USA
LB Agar	Invitrogen, Carlsbad, USA
Kanamycin	Merck, Darmstadt, Germany
2-propanol	Merck, Darmstadt, Germany
Trypan blue solution 0.4%	Merck, Darmstadt, Germany
Tween® 20	Merck, Darmstadt, Germany
Trypsine EDTA: 0.5%	PAA laboratories, Pasching, Austria
Transfection Reagent TransIT	Mirus, Madison, USA
Sodium pyruvate	Invitrogen, Carlsbad, USA
SOC outgrowth medium	New England Biolabs, Ipswich, UK
RPMI medium	Invitrogen, Carlsbad, USA
RNase Out	Invitrogen, Carlsbad, USA
Retronectin	Takara, Kusatsu, Japan
Restriction enzymes	New England Biolabs, Ipswich, UK
Proteinase K	GeneAll Biotechnology, Seoul, Korea
Protamine sulfate	MP Biomedicals, Illkirch, France
Paraformaldehyde (PFA)	Merck, Darmstadt, Germany
Skim milk powder	Merck, Darmstadt, Germany
SYPRO® Orange	Merck, Darmstadt, Germany

Restriction enzymes	New England Biolabs, Ipswich, UK
---------------------	----------------------------------

## 177 2.1.4 Antibodies and HLA-Multimers

178 **Table 4: Antibody and HLA-multimers**

Antibody	Clone and Isotype	Company/Manufacturer
anti-hCD3	UCHT-1 mIgG1 $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD137	4B4-1 mIgG1, $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD4	RPA-T4 mIgG1 $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD45	J.33 mIgG1	Beckman Coulter, Krefeld, Germany
anti-hCD45RA	HI100 mIgG2b $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-mTCR $\beta$	H57-597 Armenian Hamster IgG2, $\lambda$ 1	BD Bioscience, Franklin Lakes, USA
anti-human $\beta$ Mark TCR V $\beta$ Repertoire		Beckman Coulter, Krefeld, Germany
anti-hCD45RO	UCHL1 mIgG2 $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD5	BL1a mIgG2a	Beckman Coulter, Krefeld, Germany
anti-hCD62L	DREG-56 mIgG1 $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD8	RPA-T8 mIgG1 $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-mTCR $\beta$	H57-597 hamster IgG2 $\lambda$ 1	BD Bioscience, Franklin Lakes, USA
anti-HLA-B*07	BB7.1 mIgG1, $\kappa$	BioLegend, San Diego, USA
anti-HLA-ABC	W6/32 IgG2a, $\kappa$	BioLegend, San Diego, USA
anti-hCD80	L307.4 C3H/Bi IgG1, $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-hCD86	2331 mIgG1, $\kappa$	BD Bioscience, Franklin Lakes, USA
anti-mouse CD16/32	clone 93	BioLegend, San Diego, USA
anti-beta two microglobulin HRP	polyclonal	Thermo Fisher Scientific, Rockford, USA
Isotypes for mIgG1 $\kappa$ Abs.		BD Bioscience, Franklin Lakes, USA
Isotype for mIgG2b $\kappa$ Abs.		BD Bioscience, Franklin Lakes, USA
Isotype for IgG2, $\lambda$ 1		BD Bioscience, Franklin Lakes, USA
Isotype for mIgG2 $\kappa$		BD Bioscience, Franklin Lakes, USA
Isotype for mIgG2a		Beckman Coulter, Krefeld, Germany
MPO <sub>145</sub> -TPAQLNVL-HLA Multimer-PE	HLA-allele B*07:02	D.H. Busch, MRI Munich, Germany
Myb272-VPQAAAAI-HLA Multimer-PE	HLA-allele B*07:02	D.H. Busch, MRI Munich, Germany

## 179 2.1.5 Cytokines, TLR ligands, Prostaglandins, Growth Factors for Cell Culture

180 **Table 5: Cytokines, TLR ligands, prostaglandins, growth factors**

Cytokine	Company
human TNF- $\alpha$	Peprotech, Hamburg, Germany
human IL1- $\beta$	Peprotech, Hamburg, Germany
human IFN- $\gamma$	Peprotech, Hamburg, Germany
human IL-4	Peprotech, Hamburg, Germany
human GM-CSF	Peprotech, Hamburg, Germany
human IL-7	Peprotech, Hamburg, Germany
human IL-15	Peprotech, Hamburg, Germany
CL075	InvivoGen, San Diego, USA
FLT3LG	Peprotech, Hamburg, Germany
SCF (Stem cell factor)	Peprotech, Hamburg, Germany
PGE2 (Prostaglandine E2)	Merck, Darmstadt, Germany

## 181 2.1.6 Biochemical Assay Kits

182 **Table 6: Biochemical kits**

Kit	Company
Dynabeads Untouched <sup>TM</sup> CD8+	Invitrogen, Carlsbad, USA
HotstarTaq MasterMix Kit Plus	Qiagen, Hilden, Germany
KOD Hot Start Polymerase Kit	Merck, Darmstadt, Germany
Human CD45RO Micro Beads	Miltenyi Biotech, Bergisch Gladbach, Germany
Human CD57 MicroBeads	Miltenyi Biotech, Bergisch Gladbach, Germany
JETSTAR 2.0 Plasmid Purification Kit	Genomed, Löhne, Germany
NucleoSpin Gel and PCR Clean-up	Macherey-Nagel, Düren, Germany
mMESSAGE mMACHINE T7	Invitrogen, Carlsbad, Germany
Poly(A) Tailing Kit	Invitrogen, Carlsbad, Germany
RNeasy Mini Kit	Qiagen, Hilden, Germany
Wizard Genomic DNA Purification Kit	Promega, Madison, USA
Human IFN- $\gamma$ ELISA Set	BD Bioscience, Franklin Lakes, USA
Human TNF ELISA Set	BD Bioscience, Franklin Lakes, USA
Human IL-2 ELISA Set	BD Bioscience, Franklin Lakes, USA
Human MACSPlex Cytokine 12 Kit	Miltenyi Biotech, Bergisch Gladbach, Germany
TMB Substrate Reagent Set	BD Bioscience, Franklin Lakes, USA
PerfeCTa SYBR Green FastMix ROX	QuantaBio, Beverly, MA, USA
PerfeCTa FastMix II ROX	QuantaBio, Beverly, MA, USA
AffinityScript Multiple Temperature cDNA Synthesis Kit	Agilent Technologies, Santa Clara, USA
DNA blood and tissue kit	QIAGEN GmbH, Hilden, Germany

Intracellular Fixation & Permeabilization Buffer Set	Thermo Fisher Scientific, Waltham, USA
Human total RNA Master Panel II	Clontech Laboratories, Inc., Mountain View, USA
NEB® 5-alpha Competent E. coli	New England BioLabs Inc., Frankfurt am Main, Germany
NucleoBond® Xtra Maxi EF	MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany
Nucleospin Gel and PCR Cleanup kit	MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany
RNeasy Mini Kit	QIAGEN GmbH, Hilden, Germany

## 183 2.1.7 Buffer and Solutions

184 **Table 7: Buffer and solutions**

Buffer	Additives
FACS buffer for flow cytometry	PBS, 1% FCS
Fixation buffer	2% Paraformaldehyde
ELISA Coating buffer	100 mM NaHCO <sub>3</sub> , 30 mM Na <sub>2</sub> CO <sub>3</sub> in H <sub>2</sub> O, pH 9.5
ELISA washing buffer	PBS, 0.02% v/v Tween@20
ELISA blocking solution	PBS, 1 % v/v Skim milk powder
ACK Lysis buffer for lysis of erythrocytes	150 mM NH <sub>4</sub> Cl, 10 mM KHCO <sub>3</sub> , 0.1 mM EDTA in H <sub>2</sub> O
10xTAE buffer for DNA gel electrophoresis	0.4 mM Tris-HCl, pH 7.8
heat inactivated FCS and human serum	20' min, 58°C
Central memory T-cell isolation buffer	PBS, 2% BSA, 2 mM EDTA
Retronectin buffer for transduction	PBS, 12 µg/ml RetroNectin

## 185 2.1.8 Cell Culture Media

186 **Table 8: Cell culture media**

Medium	Composition
cRPMI	RPMI supplemented with Penicillin/Streptomycin (100 IU/ml), Sodium pyruvate (1 mM), L-Glutamine (2 mM), non-essential amino-acids (10 mM) and 10% (v/v) Fetal bovine serum
cDMEM	DMEM supplemented with Penicillin/Streptomycin (100 IU/ml), Sodium pyruvate (1 mM), L-Glutamine (2 mM), non-essential amino-acids (10 mM) and 10% (v/v) Fetal bovine serum
T-cell medium (0,22 µm filtered)	RPMI supplemented with Penicillin/Streptomycin (100 IU/ml), Gentamicin (16 µg/ml), Sodium pyruvate (1 mM), L-Glutamine (2 mM), non-essential amino-acids (10 mM), 5% (v/v) Fetal bovine serum and 5% (v/v) Human serum
Dendritic cell medium (DCM) (primary)	VLE-RPMI supplemented with 1,5% human serum
DC-medium I	VLE-RPMI supplemented with 1,5% human serum, IL-4 20 ng/ml, GM-CSF 100ng/ml

DC-medium II	VLE-RPMI supplemented with 1,5% human serum, TNF-alpha 10 ng/ml, IL1-beta 10 ng/ml, IFN-gamma 5000 IU/ml PGE2 250 ng/ml, CL075 1 µg/ml, IL-4 20 ng/ml, GM-CSF 100 ng/ml
Freezing medium	Fetal bovine serum with 10% DMSO

## 187 2.1.9 Cell Lines and Primary Cells

## 188 Table 9: Cell lines

Cell line	Culture medium	Disease / transformed	Origin
HL60	cRPMI	APL	CLS, Eppelheim, Germany
NB4	cRPMI	APL	CLS, Eppelheim, Germany
ML2	cRPMI	AML	The Cabri consortium
MV4-11	cRPMI	AML	CLS, Eppelheim, Germany
SiG-M5	cRPMI	AML	DMSZ, Braunschweig, Germany
UT7	cRPMI	AML	DMSZ, Braunschweig, Germany
LAMA84	cRPMI	CML	DMSZ, Braunschweig, Germany
K562	cRPMI	CML	ATCC, Manassas, USA
BJAB	cRPMI	Burkitt lymphoma	J. Mautner, München, Germany
C1R	cRPMI	EBV-transformed	S. Stevanović, Tübingen, Germany
Molt4	cRPMI	T-ALL	CLS, Eppelheim, Germany
NSO-IL-15	cRPMI	Mouse myeloma	S. Riddell, Seattle, USA
KG-1a	cRPMI	AML	CLS, Eppelheim, Germany
SET2	cRPMI	AML	DMSZ, Braunschweig, Germany
293Vec-RD114	cDMEM	Human embryonic kidney cells	Biovec pharma, Québec, Canada
T2	cRPMI	T-B-Lymphoblast (hybrid)	ATCC, Manassas, USA
MV4-11	cRPMI	AML	CLS, Eppelheim, Germany
Jurkat, clone E6-1	cRPMI	Acute T-cell leukemia	AG Ruland, MRI, München, Germany

189

## 190 Table 10: HLA-typing of Lymphoblastoid cell lines (LCL)

LCL cell line	HLA-A*	HLA-B*
AMALA	02:17/ --	15:01/ --
BM21	01:01/ --	41:01/ --

Cells	Culture medium	Origin
PBMC	TCM	Healthy donors
Dendritic cells	DCM (basic, day 0, day 2)	Healthy donors
T lymphocytes	TCM	Healthy donors
PBMC from CML patients	TCM	CML patients

## 193 2.1.11 Primers

194 All primers were synthesized and delivered lyophilized by Sigma-Aldrich (Merck), Ger-  
 195 many and dissolved in DEPC water to a final concentration of 100  $\mu$ M. Table 12 lists all  
 196 primer sequences in 5'  $\rightarrow$  3' direction.

197 **Table 12: TCRVA and TCRVB primer**

## 209 2.2 Methods

### 210 2.2.1 Cell Culture

211 Cell culturing was done under sterile condition in a safety workbench. Human blood,  
212 patient material, cell lines with biosafety level S2 and retroviral transductions were per-  
213 formed according to S2 safety guidelines. All tumor cell lines were periodically tested for  
214 the absence of mycoplasma infections. Usually, cell lines grown in suspension or adherent  
215 cell lines were split according to their proliferation kinetics to maintain optimal cell line  
216 stability. Suspension cell lines were split by replacing the used medium or adding it to  
217 expand the cells. In the case of adherent cell lines, except the 293Vec-RD114, the cells  
218 were treated with 1x trypsin/EDTA/PBS solution. After detachment of the cells, the re-  
219 action stopped by adding cDMEM supplemented with 20% FCS followed by a washing  
220 step at 500 g for 5' min and resuspension in fresh cDMEM.

#### 221 2.2.1.1 Cell counting

222 The cell count was assessed by using a Neubauer chamber. To discriminate living cells  
223 from dead cells, trypan blue [1%] solution was used. The cell concentration of living cells  
224 was calculated using the following formula:

$$225 \quad \frac{\text{cell concentration}}{\text{ml}} = \frac{\text{cells counted in all 4 areas} \times \text{dilution factor}}{4} \times 10^4$$

#### 226 2.2.1.2 Freezing and thawing of eukaryotic cells

227 Cells which have chosen for cryopreservation in liquid nitrogen were centrifuged at 500 g  
228 for 5' min and resuspended in DMSO supplemented with 10% FCS. Transferred to 1.8 ml  
229 cryotubes (Merck) the aliquots were stored in freezing container to ensure 1°C/min cool-  
230 ing rate in a -80°C freezer. Subsequently, the cryotubes were transferred to a liquid nitro-

231 gen cryopreservation tank. For cell thawing, the samples were removed from liquid ni-  
232 trogen and placed into a water bath at 37°C. Immediately after thawing, the cells were  
233 transferred to a 15 ml or 50 ml falcon and washed with RPMI at 500 g for 5' min. After-  
234 wards, the cells were ready to use for downstream applications.

#### 235 2.2.1.3 Isolation and activation of PBMC from EDTA-blood samples

236 Biocoll density gradient centrifugation was used to isolate PBMC out of whole blood  
237 withdrawals dosed with EDTA. The whole blood was diluted 1:1 with RPMI and 35 ml  
238 of the dilution was carefully covered on 15 ml Biocoll reagent (Merck) in a 50 ml falcon.  
239 After 20' min of centrifugation at 880 g with disabled breaks at RT, the buffy coat was  
240 collected into a new 50 ml falcon and washed twice with RPMI at 500 g for 5' min. Fi-  
241 nally, the PBMC were resuspended in TCM to a final concentration of  $2 \times 10^6$  cell/ml. For  
242 activation, 2 ml of the PBMC were transferred to a cell culture treated 12-well plate and  
243 incubated with 50 U/ml hIL-2 and 30 ng/ml OKT3 for 48 h at 37°C.

#### 244 2.2.1.4 Purification of CD4<sup>-</sup>/CD45RA<sup>-</sup>/CD62L<sup>+</sup> T<sub>CM</sub>

245 Purification of CD8<sup>+</sup> T<sub>CM</sub> was done using 250 ml blood from healthy donors. First, the  
246 PBMCs were isolated using the Biocoll (Merck) separation protocol (chapter 2.2.1.3).  
247 Second,  $1 \times 10^8$  PBMCs were incubated rotating with 40 µl of an anti-human CD4-APC-  
248 (BD) and 40 µl of an anti-human CD45RA-APC antibody (BD) for 20' min in a final  
249 volume of 800 µl isolation buffer at 4°C. After a washing step with isolation buffer, the  
250 antibody stained PBMCs were adjusted to  $1 \times 10^8$  cells per 1 ml containing 800 µl isolation  
251 buffer and 200 µl anti-APC magnetic beads (Miltenyi Biotec). Following a rotary incu-  
252 bation step at 4°C for 20' min and an additional washing step, the CD4<sup>+</sup> and CD45RA<sup>+</sup>  
253 cells were depleted using LD columns (Miltenyi Biotec) for magnetic cell separation in  
254 500 µl isolation buffer per  $1 \times 10^8$  cells according to the manufacturer protocol. Third, the  
255 remaining cells were incubated with 20 µl anti-human CD62L-PE antibody in a final vol-  
256 ume of 100 µl isolation buffer per  $1 \times 10^7$  cells rotating at 4°C for 20' min. After incubation,

257 the cells were washed and stained for 20' min rotary at 4°C with 20 µl anti-PE beads in a  
258 final volume of 100 µl per  $1 \times 10^7$  cells. Followed by an additional washing step, the cells  
259 were resuspended in 500 µl isolation buffer and separated via a LS-column according to  
260 the manufacturer's instruction (Miltenyi Biotec). The phenotype of remaining CD4<sup>-</sup>  
261 CD45RA<sup>-</sup>CD62L<sup>+</sup> cells was analyzed by flow cytometry and activated using anti-human  
262 CD3 and CD28 beads (chapter 2.2.1.5).

#### 263 2.2.1.5 Activation of PBMCs and CD4<sup>-</sup>/CD45RA<sup>-</sup>/CD62L<sup>+</sup> T<sub>CM</sub>

264 The activation of PBMCs or CD4<sup>-</sup>/CD45RA<sup>-</sup>/CD62L<sup>+</sup> T<sub>CM</sub> was done using anti-CD3 and  
265 CD28 labeled beads (Merck) according to the manufacturer's instructions. 50 µl bead was  
266 used per  $2 \times 10^6$  cells in a final volume of 2 ml TCM supplemented with 30 U/ml hIL-2.  
267 The cells were activated for two days in a 12-well tissue culture plate (TPP).

#### 268 2.2.1.6 Transfection of 293Vec-RD114 using pMP71

269 The transduction of T-Lymphocytes and tumor cell lines follows a six days protocol start-  
270 ing with plating of the packaging cell line 293Vec-RD114 (biovec pharma) with  $2.5 \times 10^5$   
271 cells per well in a 6-well cell culture plate in 3 ml cDMEM. The confluence of the cells  
272 should be around 60% after 24 h of culture. For the transfection of the 293Vec-RD114  
273 200 µl, serum-free DMEM was supplemented with 3 µl TransIT reagent (Mirus Bio LLC)  
274 and was incubated after thoroughly mixing for 20' min at RT. Following this, 1 µg of  
275 pMP71 containing the gene of interest was added to the reaction, gently mixed and incu-  
276 bated for an additional 30' min at RT. Finally, the transfection mix was added to the  
277 plated 293Vec-RD114 cells and incubated for 48 h at 37°C. Subsequently, half of the  
278 supernatant was harvested and filtered through a 0.45 µm syringe filter and used for the  
279 transduction of target cells. The remaining supernatant was harvested 24 h later, also fil-  
280 tered and used for an additional round of transduction.

281 2.2.1.7 Retroviral transduction of activated PBMC and T<sub>CM</sub>

282 Activated PBMC and T<sub>CM</sub> were transduced twice on two consecutive days in non-cell  
283 culture treated 24-well plates coated with 12.5 mg/ml RetroNectin (Takara) in PBS. The  
284 solution was plated to each well and incubated for 24 h followed by removal of the solu-  
285 tion and subsequently blocking with 500 µl of a 2% BSA/PBS solution for 30' min at  
286 37°C. After blocking, the wells were washed twice with 2 ml PBS supplemented with  
287 2.5% (v/v) HEPES and were ready to use for retroviral transduction. 1x10<sup>6</sup> activated  
288 PBMC or T<sub>CM</sub> in a final volume of 1 ml in TCM were supplemented with 200 U/ml hIL-  
289 2, 2% HEPES and 8 µg/ml protamine sulfate and seeded in one well of the RetroNectin-  
290 coated 12-well plates. Subsequently, 1 ml of viral supernatant harvested from the trans-  
291 fection of 293Vec-RD114 cells (see chapter 2.2.1.6) was pipetted to the activated PBMC  
292 or T<sub>CM</sub> and centrifuged for 90' min at 933 g and 32°C. After that, the cells incubated for  
293 24 h at 37°C, and the transduction was repeated a second time accordingly after resus-  
294 pension and washing of the cells. Finally, the cells were resuspended in TCM supple-  
295 mented with hIL-7 and hIL15 at a final concentration of 5 ng/ml. Five days after the sec-  
296 ond transduction the transduction efficiency was analyzed by flow cytometry (see chapter  
297 2.2.5.1).

## 298 2.2.1.8 Retroviral transduction of tumor cell lines

299 The retroviral transduction of tumor cell lines with pMP71 containing the HLA-re-  
300 striction elements, the MPO-protein sequences or the MPO-minigenes was analog to the  
301 retroviral transduction of activated PBMC and T<sub>CM</sub> except for the following variations.  
302 Instead of TCM, cRPMI was used and no hIL-2 was added to the tumor cell lines during  
303 the transduction protocol (see chapter 2.2.1.7).

304 2.2.1.9 Isolation of CD8<sup>+</sup> naïve T cells

305 PBMC were isolated according to chapter 2.2.1.3 but not activated. CD8<sup>+</sup> T cells were  
306 negatively sorted using the CD8 untouched isolation kit (Thermo Fisher Scientific) ac-  
307 cording to the procedure of the manufacturer. CD8<sup>+</sup> enriched T cells subsequently were  
308 used for the depletion of CD45RO<sup>+</sup> and CD57<sup>+</sup> cells with magnetic microbeads (Miltenyi  
309 Biotec) according to the manufacturer instructions. The phenotype of the obtained  
310 CD8<sup>+</sup>CD45RO<sup>-</sup>CD57<sup>-</sup> naïve T cells was verified by flow cytometry.

311 2.2.1.10 Expansion of peptide specific CD8<sup>+</sup> naïve T cells

312 The generation of dendritic cells (DC) used for the single HLA-mismatch (sHLAm) stim-  
313 ulation was done as previously described [43]. After Isolation of PBMCs (see chapter  
314 2.2.1.3) 150 million PBMCs were used to adhere monocytes to the bottom of an 80 cm<sup>2</sup>  
315 Nunclon-surface flask via plate adherence in 12 ml pre-warmed (37°C) DC-medium for  
316 1.5 h at 37°C. Afterward, the cells which have not been attached to the bottom of the flask  
317 were carefully removed by gentle rinsing the cells with DC-medium for three times. The  
318 remaining adherent cells were cultivated with 15 ml DC-medium II for 48 h. Finally, the  
319 maturation was induced by adding 500 µl DC-medium III to the cell culture. After 24 h  
320 of cultivation, the DC were detached by washing the flask three times with 12 ml PBS +  
321 0.5% HS and additional use of a cell scraper. The result of DC maturation was verified  
322 by flow cytometry. Mature DC were washed twice in OptiMEM. Three million DC were  
323 resuspended in 200 µl cold (4°C) OptiMEM and transferred to a 4 mm electroporation  
324 cuvette to chill for 3' min on ice before electroporation. Immediately before the electro-  
325 poration in a *Gene Pulser Xcell* Electroporation System (Bio-Rad) 40 µg of in-vitro tran-  
326 scribed HLA-eGFP-RNA (see chapter 2.2.2.11) was added to the DC and resuspended  
327 with a 200 µl tip. The protocol of the electroporator was as follows: exponential protocol,  
328 300 µF, and 300 V. Directly after the electroporation the DC were transferred to a well  
329 containing 3 ml pre-warmed DC-medium of a 6-well cell culture plate (TPP) and cultured

330 overnight at 37°C. The DC with transient HLA-eGFP expression were washed twice with  
331 AIM-V medium and pulsed with MPO-peptides in 100 µl AIM-V at a final concentration  
332 of 0.1 µM for 2h at 37°C. Finally, the DC were washed twice with RPMI and co-cultured  
333 with CD8+ naïve T cells (see chapter 2.2.1.10) of the same donor in 500 µl TCM supple-  
334 mented with 30 ng/ml hIL-21 at an effector to target ratio of 10:1 for three days in a well  
335 of a 48-well cell culture plate. During the expansion of peptide-specific CD8+ naïve  
336 T cells, every 2-3 days hIL-7 and hIL-15 was added to the culture to a final concentration  
337 of 5 ng/ml, and if required, the cells were split with fresh TCM. At day 10 of co-culture,  
338 the cells were re-stimulated with  $\gamma$ -irradiated (30 Gy) C1R cells transgenic for the desired  
339 HLA-allele pulsed with 0.1 µM MPO-peptide. The ratio between effector and target cells  
340 was 10:1 for the re-stimulation in a final volume of 2 ml TCM supplemented with  
341 30 ng/ml hIL-21 (2 million expanded T cells: 0.2 million C1R cells) in a well of a 12-  
342 well cell culture plate. Again, every 2-3 days hIL-7 and hIL-15 was added to the culture  
343 to a final concentration of 5 ng/ml, and if necessary, the cells were split. At day 16 after  
344 the start of co-culture the frequency of peptide-specific T-cells was measured by multimer  
345 staining (see chapter 2.2.5.3).

#### 346 2.2.1.11 CD137 allo-depletion and sort of MPO-HLA-tetramer positive T cells

347 Before the sort of peptide-specific T cells by MPO-HLA-tetramers the cells derived from  
348 the sHLAm approach were allo-depleted using  $\gamma$ -irradiated (30 Gy) C1R cells, transgenic  
349 for the HLA-allele used in the sHLAm approach. The HLA-transgenic C1R cells without  
350 any peptide pulsing were co-cultured overnight with the stimulated T cells to elicit MPO-  
351 peptide independent HLA-alloreactivity and CD137 upregulation on the surface of allo-  
352 reactive T cells. CD137<sup>+</sup> T cells were depleted by MACS separation using the CD137  
353 MicroBead Kit (Miltenyi Biotec) according to the manufacturer instructions. The remain-  
354 ing T cell population was FACS-sorted by MPO-HLA-tetramers to get peptide-specific  
355 T cells (see chapter 2.2.5.3).

## 356 2.2.1.12 Limited dilution cloning of T-cell lines

357 Peptide-specific T cells sorted by MPO-HLA-tetramers were cloned by limited dilution  
 358 to a final concentration of 0.5 to 1.0 sorted T cells per well in a 96-well cell culture plate  
 359 (TPP). These cells were co-cultured with 50.000 cells of  $\gamma$ -irradiated (30 Gy) PBMCs  
 360 from three different donors (feeder cells) in TCM supplemented with 30 ng/ml OKT-3  
 361 and 50 U/ml hIL-2. Continuing, hIL-2 was added twice per week at the same concentra-  
 362 tion. After two weeks, the cloned T cells were analyzed for peptide specificity using 50  $\mu$ l  
 363 of T cell suspension. Another 50  $\mu$ l were used for RNA isolation using the TRIzol reagent  
 364 protocol (see chapter 2.2.2.2). Remaining T cells were chosen for another round of ex-  
 365 pansion with feeder cells as described before.

## 366 2.2.2 Molecular biology methods

## 367 2.2.2.1 Restriction digest, Ligation, and Transformation

368 Vector DNA and PCR-products were digested for 2 h at 37°C using different restriction  
 369 enzymes (New England Biolabs) in a digestion mix indicated in Table 17. After digestion,  
 370 the enzymes were heat-inactivated at 65°C for 20' min followed by gel purification after  
 371 separation using agarose gel electrophoresis in case of vector DNA or direct purification  
 372 using the *Nucleospin Gel and PCR Cleanup Kit* (Macherey-Nagel) in case of PCR-prod-  
 373 ucts (inserts).

374 **Table 17: Digestion mix for the restriction enzymes NotI, EcoRI or Sall**

Reagent	Concentration	Vector	Insert
Vector DNA or PCR-product	variable	15 $\mu$ l	23.5 $\mu$ l
Buffer "O"	10x	10 $\mu$ l	10 $\mu$ l
NotI	10.000 U/ml	2 $\mu$ l	2 $\mu$ l
EcoRI or Sall	20.000 U/ml	2 $\mu$ l	2 $\mu$ l
DEPC water		ad 100 $\mu$ l	ad 100 $\mu$ l

375

376

377 Ligation of digested and purified vector DNA and inserts was done using the T4 ligase  
 378 according to the following equation:

$$379 \text{ Volume of insert} = n * 1 \mu\text{l Vector} * \frac{C \text{ Vector}}{C \text{ Insert}} * \frac{\text{length of Insert [bp]}}{\text{length of Vector [bp]}}$$

380

381  $n = \text{molar ratio of insert to vector}; C = \text{concentration}; bp = \text{base pair}$

382

383 The ligation mix and the incubation time is shown in Table 18:

384 **Table 18: Reagent mix for insert ligation**

Reagent	Volume	Incubation
Digested vector	1 $\mu\text{l}$	1. 16 h, 16°C 2. 20' min, 65°C
Digested insert	variable	
10x T4 buffer	1 $\mu\text{l}$	
T4 ligase	1 $\mu\text{l}$	
DEPC water	ad 10 $\mu\text{l}$	

385

386 After the ligation of vector and insert the completed vector construct was clonal amplified  
 387 by NEB5 $\alpha$  competent *E. coli* (New England Biolabs). The transformation was performed  
 388 according to the manufacturer's instructions with the following modifications. Competent  
 389 *E. coli* were thawed on ice for 10' min 1  $\mu\text{l}$  containing 100 ng vector construct was pipet-  
 390 ted to the bacteria and carefully flicked five times. After incubation on ice for an addi-  
 391 tional 30' min, a heat-shock of 42°C for exact 30 s was performed, and the tube was  
 392 replaced on ice for another 5' min. The bacteria were gently mixed with 400  $\mu\text{l}$  SOC me-  
 393 dium (RT) and incubated for 1 h at 37°C and 250 rpm. Afterward, several dilutions of the  
 394 bacteria mix were plated on ampicillin (100  $\mu\text{g/ml}$ ) supplemented LB-agar plates and in-  
 395 cubated overnight at 37°C. Finally, grown colonies of bacteria were picked with pipette  
 396 tips and incubated for expansion in 3 ml LB-medium supplemented with ampicillin  
 397 (100  $\mu\text{g/ml}$ ) for at least 6 h on a shaker at 250 rpm at 37°C.

398 The amplified vector constructs were purified using the *JETSTAR™ 2.0 Plasmid Purifi-*  
399 *cation Kit* and protocol (Genomed). 2 ml of the bacteria mix was used for the purification,  
400 and the isolated vector constructs were verified after a control digest by gel electrophore-  
401 sis (see chapter 2.2.2.6 and digest protocol above) and vector sequencing (MWG Eu-  
402 rofins). Correct vector construct was chosen for an additional round of transformation,  
403 expansion, and purification, as described above with the following modifications: 0.5 ml  
404 of the heat-shock transformed bacteria mix after 6 h of incubation, were used to inoculate  
405 250 ml of LB-medium supplemented with ampicillin (100 µg/ml). The bacteria were ex-  
406 panded overnight at 37°C and 250 rpm. For the purification of vector constructs, the en-  
407 dotoxin-free *NucleoBond® Xtra Maxi EF* kit and protocol (Macherey Nagel) was used  
408 according to the manufacturer's instructions and stored until use at -20°C. The vector  
409 sequence was confirmed again by Sanger sequencing (MWG Eurofins).

#### 410 2.2.2.2 RNA isolation

411 RNA was isolated out of different AML cell lines and T-cell clones. Whenever enough  
412 cell material was available (more than  $1 \times 10^6$  cells), the cell pellets were firmly resus-  
413 pended in 4°C cold 1 ml TRIzol reagent. Cell pellets not exceeding  $1 \times 10^6$  cells were re-  
414 suspended in only 200 µl TRIzol reagent, and in case of T-cell clones, 10 µg yeast RNA  
415 was added. The samples were incubated for 5' min at RT followed by addition of 200 µl  
416 (40 microliter for T-cell clones in 200 microliter TRIzol) chloroform and subsequent in-  
417 cubation for 10' min at RT. Afterward, the samples were centrifuged for 15' min at 15.000  
418 g and 4°C. For RNA precipitation the RNA phases were transferred to new tubes contain-  
419 ing 500 µl 2-propanol followed by incubation for 1 h at -20°C and centrifugation for 20'  
420 min at 15.000 g and 4°C. After removal of the supernatants, the pellets were washed with  
421 1 ml 75% ethanol and centrifuged again for 5' min at 15.000 g at 4°C. Finally, the dried

422 pellets were resuspended in 21.5  $\mu$ l DEPC water, and 1.5  $\mu$ l were used for the determina-  
423 tion of RNA concentration using a *NanoDrop ND-1000* (PeqLab). Until the use in down-  
424 stream applications the RNA was stored at  $-80^{\circ}\text{C}$ .

425 2.2.2.3 cDNA synthesis from RNA templates  
 426 Isolated RNA samples (see chapter 2.2.2.2) were reverse transcribed into cDNA (com-  
 427plementary DNA) with the *Affinity Script cDNA Synthesis Kit* (Agilent Technologies)  
 428 according to the manufactures' protocol except for the following variations: see Table 19.  
 429 Until the use in downstream applications the cDNA was stored at -20°C.

430 **Table 19: cDNA synthesis using the *Affinity Script cDNA Synthesis Kit***

Steps	Reagent	Volume	Incubation
1.	RNA (1 µg/µl)	1 µl	1. 65°C, 5' min
2.	oligo(dT) Sigma (500 ng/µl)	1 µl	2. RT, 10' min
3.	DEPC water	11.5 µl	3. 4°C, ∞
Steps	Reagent	Volume	Incubation
4.	Affinity Script Puffer	2 µl	1. 47,5°C, 1 h 2. 70°C, 15' min
5.	dNTPs Fermentas (10 mM)	2 µl	
6.	RNase out (Invitrogen)	0.5 µl	
7.	Affinity Script	1 µl	

431 2.2.2.4 PCR using KOD polymerase  
 432 For the amplification of genes of interest, RNA out of cell lines and T-cell clones were  
 433 reverse transcribed to cDNA (see chapter 2.2.2.3) and used as a template in a PCR reac-  
 434tion. The different primers used for the PCR cycling are listed in Table 12 and Table 13.  
 435 For the amplification, the *KOD Hot Start Polymerase* kit (Merck) was used, and the re-  
 436action mixture (Table 20) was set up in a 0.5 ml PCR reaction tube. The PCR (Table 21)  
 437 was performed on a Biometra *TGradient Thermocycler* (Analytik Jena).

438 **Table 20: PCR reaction mix using KOD polymerase**

Volume	Reagent
10 µl	10x KOD buffer
10 µl	dNTPs (2 mmol/l)
6 µl	MgSO <sub>4</sub> (25 mmol/l)
3 µl	forward Primer (15 mmol/L)
3 µl	Reverse Primer (15 mmol/L)
2 µl	cDNA
2 µl	KOD polymerase
ad 100 µl	DEPC water

439

440 **Table 21: PCR program using KOD polymerase**

Temperature	Time	Cycles	Reaction
95°C	2' min	1x	Pre-denaturation
95°C	30 s		Denaturation
55°C	30 s	35x	Annealing
70°C	1' min		Extension
70°C	10' min	1x	Final extension
4°C	∞	1x	Infinite hold

441

## 442 2.2.2.5 TCR alpha and beta repertoire PCR

443 For the analysis of the TCR alpha and beta repertoire, RNA of T-cell clones was isolated  
444 and reverse transcribed into cDNA (see chapter 2.2.2.2 and 2.2.2.3). Various primers were  
445 used to cover the different regions of the variable alpha and variable beta domain in order  
446 to analyze the TCR repertoire (Table 12). The PCR was performed using the *HotStar*  
447 *MasterMix Plus* reagents (Qiagen) in V-alpha, or V-beta PCR reaction mixes shown in  
448 Table 22 and Table 23 using a Biometra *TGradient Thermocycler* with the setup shown  
449 in Table 24. Specific PCR products were extracted from an agarose gel and the DNA  
450 sequenced after purification with the respective V-alpha and V-beta primer by Eurofins  
451 MWG.

452 **Table 22: PCR reaction mix for TCR V-alpha repertoire**

Reagent	Volume
cDNA	0.55 µl
P-5'aST (5 µmol/l)	1.5 µl
P-3' aST (5 µmol/l)	1.5 µl
3'-Ca (5 µmol/l)	2 µl
Va-Primer (5 µmol/l)	3 µl
Coral load	2.5 µl
DEPC water	1.4 µl
HotStar MasterMix	12.5 µl

453

454 **Table 23: PCR reaction ingredients for TCR V-beta repertoire**

Reagent	Volume
cDNA	0.55 $\mu$ l
P-5' $\beta$ ST (5 $\mu$ mol/l)	1.5 $\mu$ l
P-3' $\beta$ ST (5 $\mu$ mol/l)	1.5 $\mu$ l
3'C $\beta$ II (5 $\mu$ mol/l)	2.0 $\mu$ l
V $\beta$ -Primer (5 $\mu$ mol/l)	3 $\mu$ l
Coral load	2.5 $\mu$ l
DEPC water	0.29 $\mu$ l
HotStar MasterMix	12.5 $\mu$ l

455 **Table 24: PCR program TCR alpha and beta repertoire**

Temperature	Time	Cycles	Reaction
95°C	15' min	1x	Pre-denaturation
94°C	1' min		Denaturation
54°C	1' min	35x	Annealing
72°C	1' min		Extension
72°C	10' min	1x	Final extension
4°C	$\infty$	1x	Infinite hold

456

## 457 2.2.2.6 Agarose gel electrophoresis

458 Agarose gel electrophoresis was performed to verify the correct length of PCR constructs  
459 or vector constructs. The gel was prepared using 1.0-1.5% agarose in 1x TAE (TRIS-  
460 Acetate-EDTA-Puffer) buffer followed by heating of the suspension till the complete dis-  
461 solution of agarose. Before transfer into a gel chamber, ethidium bromide was added to a  
462 final concentration of 0.25  $\mu$ g/ml. If necessary, the samples were prepared by adding  
463 loading dye to a 1x dilution. As references 100 bp or 1 kb DNA ladders were used. The  
464 run of the gel electrophoresis was performed on a *Compact M Horizontal Gel Electro-*  
465 *phoresis Apparatus* (Biometra) with 100 V for 45' min in 1x TAE buffer. For the visuali-  
466 zation of bands within the gel, the *BioDocAnalyze Gel documentation system* (Biometra)  
467 was used.

## 468 2.2.2.7 PCR product purification out of agarose gels

469 For the purification of PCR products out of agarose gels, the *Nucleospin Gel and PCR*  
470 *Cleanup kit* and protocol (Macherey-Nagel) was used. In the final step of the protocol,  
471 the PCR product was eluted in 20 µl DEPC water. The concentration was analyzed using  
472 the NanoDrop ND-1000 spectrophotometer.

## 473 2.2.2.8 In-silico TCR reconstruction using IMGT vQuest and BLAST

474 After performing the TCR repertoire (see chapter 2.2.2.5), purification (see chapter  
475 2.2.2.7) and Sanger sequencing of PCR products (MWG Eurofins), the sequences were  
476 used for reconstruction of TCR domains. To identify the complementarity determining  
477 region 3 (CDR3) and the VDJ-segments (variable (V), diversity (D), joining (J)), a data-  
478 base search was performed using the IMGT vQuest platform. Missing sequence parts not  
479 covered by the TCR repertoire were reconstructed using reference TCR sequences avail-  
480 able at the NCBI server using the Basic Local Alignment Search Tool (BLAST) and the  
481 Ensembl browser. To verify the sequences of the alpha and the beta domain, primers were  
482 designed (Sigma-Aldrich) to amplify both chains from cDNA, reverse transcribed from  
483 isolated RNA (see chapter 2.2.2.3) of peptide-specific T-cell clones.

## 484 2.2.2.9 Optimization and murinization of TCR sequences

485 For the enhanced surface presentation and reduced miss-pairing of exogenous TCR alpha  
486 and beta domains with endogenous TCR of recipient T cells after retroviral transduction  
487 (see chapter 2.2.1.7), a bicistronic vector element was designed containing both TCR do-  
488 mains linked with a P2A element [96]. Also, the constant human domains (TRAC and  
489 TRBC) were substituted by murine constant domains as previously described [97]. Be-  
490 sides a new cysteine disulfide bond between position S211C and T543C, the whole con-  
491 struct was codon optimized (Genscript) to improve the expression in human transgenic T  
492 cells [98] and finally synthesized by Genscript. The complete sequence (see appendix)  
493 was cloned into the vector pMP71 for retroviral transduction into recipient T cells.

494 2.2.2.10 qPCR using SYBR Green for PSMB subunits  
 495 Total RNA was isolated from either not treated or IFN- $\gamma$  pretreated (24 h, 250 U/ml)  
 496 AML/APL cell lines using the TRIzol reagent (see chapter 2.2.2.2). 1  $\mu$ g of isolated RNA  
 497 was used for reverse transcription into cDNA (see chapter 2.2.2.3) and the QuantaBio  
 498 PerfeCTa® SYBR® Green FastMix®, ROX™ reagent (Quantabio) was used to set up  
 499 the master mix for PCR reactions (Table 25). Semi-quantitative real-time PCR (qPCR)  
 500 was performed using the StepOnePlus system (Thermo Fisher Scientific) (Table 26). Pri-  
 501 mers specific for the proteasomal subunit sequences PSMB8, PSMB9 and PSMB10 (Ta-  
 502 ble 13) were used for the qPCR. The PSMB expression was relatively quantified by nor-  
 503 malization to the geometric mean of the housekeeping genes HPRT1, GAPDH and  
 504 HMBS using the delta/delta CT method [99]. As a reference, total RNA from bone mar-  
 505 row cells of healthy donors was used.

506 **Table 25: qPCR reaction using SYBR Green**

Reagent	Volume
PerfeCTa SYBR Green FastMix, ROX	10 $\mu$ l
Primer forward (250 nM)	0,5 $\mu$ l
Primer reverse (250 nM)	0,5 $\mu$ l
cDNA	2 $\mu$ l
DEPC water	7 $\mu$ l

507 **Table 26: qPCR program StepOnePlus using SYBR Green for PSMB**

Step	Temp.	Ramp rate	Time	Cycles	Stage	Signal Acquisition
1	50°C		2' min	1x	Holding	step and hold
2	95°C		3' min	1x		
3	95°C		3 s	40x	Cycling	
4	65°C		30 s			
5	95°C		15 s		Melt curve	
6	65°C	+ 0.3°C	15 s	1x		
7	95°C		15 s			

508

509 2.2.2.11 In-vitro transcription of HLA-RNA for DC electroporation  
510 Tumor cell lines and DC were electroporated (see chapter 2.2.1.10) with mRNA coding  
511 for HLA-P2A-eGFP. The mRNA was in-vitro transcribed (ivt) according to the  
512 mMESAGE mMACHINE® T7 Transcription Kit protocol (Thermo Fisher Scientific)  
513 using linearized pcDNA3.1–HLA-P2A-eGFP vector constructs. In the next step, ivt-RNA  
514 was polyadenylated using the Ambion™ Poly(A) Tailing Kit protocol (Thermo Fisher  
515 Scientific). A NanoDrop ND-1000 spectrophotometer was used to measure the yield of  
516 ivt-RNA at the end. Efficiency was tested using 10 µg of ivt-RNA for electroporation of  
517 the Jurkat cell line following the protocol in chapter 2.2.1.10. Each batch of ivt-RNA was  
518 stored at -80°C.

### 519 2.2.3 Analyses of T-cell lines, T-cell clones, and TCR-transgenic T cells

#### 520 2.2.3.1 Co-incubation of effector and target cell lines

521 Co-incubation assays of effector and target cells were performed using 10.000 – 100.000  
522 T cells per well in a 96-well cell culture plate (TPP) by adding target cells in different  
523 ratios according to the requirements of the assay in a final volume of 200 µl TCM. The  
524 cells were co-incubated for 4 – 20 h at 37°C. Wherever necessary the target cells were  
525 pulsed with peptides in AIM-V medium at different concentrations for 2 h at 37°C fol-  
526 lowed by two washing steps with RPMI and final resuspension in TCM before the use in  
527 the co-incubation assay.

#### 528 2.2.3.2 IFN-γ and hIL-2 ELISA

529 IFN-γ and hIL-2 ELISA were performed using the supernatants of co-incubation assays  
530 according to the manufacturer instructions using the BD *OptEIA*™ human ELISA sets  
531 with modifications for the different cytokines:

532 IFN-γ and hIL-2: Capture antibody dilutions used for the coating of 96-well ELISA plates  
533 were 1:250 and incubation was done overnight at 4°C. The standards of both cytokines

534 were prepared in TCM by serial dilution to meet concentrations ranging from 1000 pg/ml  
535 (for IFN- $\gamma$ ) or 500 pg/ml (for hIL-2) to 31.25 or 15.63 pg/ml, respectively, and blank con-  
536 trols. If not stated otherwise, 50  $\mu$ l of supernatant from the co-culture and standard was  
537 used per well. For detection, 100  $\mu$ l blocking solution containing a 1:250 dilution of anti-  
538 IFN- $\gamma$ - or a 1:500 dilution of anti-hIL-2-enzyme conjugate was used. The final develop-  
539 ment was done using 100  $\mu$ l per well of the BD *OptEIA*<sup>TM</sup> TMB substrate reagent set. The  
540 reaction was stopped after the standard was obvious by adding 50  $\mu$ l of sulfuric acid. The  
541 ELISA was measured with a Tecan Sunrise photometer using the Magellan software, set-  
542 ting the absorbance to 450 nm and the reference channel to 570 nm. Whenever the meas-  
543 ured OD-values for the samples exceeded the OD-values of the highest standard condi-  
544 tion, the ELISA was repeated using dilutions of the remaining supernatants of co-cultures.

#### 545 2.2.3.3 Functional avidity of TCR

546 For the measurement of the functional avidity, supernatants of co-cultures (see chapter  
547 2.2.3.1) of TCR-transgenic T cells and the target cell line KG-1a-B7 or C1R-B7, pulsed  
548 with graded amounts of MPO-peptides ranging from 20  $\mu$ M to 1 pM, were analyzed by  
549 IFN- $\gamma$  ELISA (see chapter 2.2.3.2). The effector to target ratio was set to 1:1 comprising  
550 20.000 cells per party.

#### 551 2.2.3.4 $K_{\text{off}}$ -measurements of TCR

552 The  $k_{\text{off}}$ -measurements and the calculations of dissociation half-lives of the MPO-TCRs  
553 were performed by Manuel Effenberger (Institut für Medizinische Mikrobiologie, Immu-  
554 nologie und Hygiene, Munich, Germany). A detailed description of the measurement pro-  
555 tocol was reported previously [81].

#### 556 2.2.3.5 Effector to target ratio titration

557 Effector to target ratio titrations followed the underlying protocol for co-incubation as-  
558 says (see chapter 2.2.3.1). MPO-TCR-transgenic T cells were serially diluted fifteen

559 times 1:1 to meet effector to target ratios ranging from 5:1 to calculated 0.00031:1. Here,  
560 the actual T-cell number started from 100.000 T cells per well of a 96-well cell culture  
561 plate down to six T cells per well pipetted to the number of 20.000 NB4-B7 target cells  
562 in a final volume of 200  $\mu$ l TCM. The controls comprised either only T cells (20.000 cells  
563 per well) or only target cells (20.000 NB4-B7 cells per well). Supernatants were harvested  
564 either after 4 h or 20 h of co-culture and were analyzed by IFN- $\gamma$  ELISA (see chapter  
565 2.2.3.2). Also, cytotoxicity using the remaining cells after co-culture were analyzed by  
566 flow cytometry for both time points (see chapter 2.2.3.6).

#### 567 2.2.3.6 Cytotoxicity measured by flow cytometry

568 The cytotoxicity of TCR-transgenic T cells against target cells was analyzed after co-  
569 incubation (see chapter 2.2.3.1 and 2.2.3.5). Remaining cells after co-culture were stained  
570 with 7-AAD and analyzed by flow cytometry (see chapter 2.2.5). For the calculation of  
571 percentages of cytotoxicity, the following procedure was used: First, the absolute number  
572 of remaining HLA-B7eGFP target cells was quantified using the AccuCheck counting  
573 beads (Thermo Fisher Scientific) according to the manufacturer recommendations:

574

$$575 \quad \text{Absolute count (cells}/\mu\text{l)} = \frac{\text{number of remaining target cells counted}}{\text{total number of beads counted}} * \text{beads per } \mu\text{l}$$

576

577 Subsequently, the absolute target cell count per  $\mu$ l was used to calculate the cytotoxicity:

578

$$579 \quad \text{Cytotoxicity (\%)} = \left( 1 - \left( \frac{\text{absolute count of remaining target cells}}{\text{mean of remaining target cell count of controls}} \right) \right) * 100$$

## 580 2.2.4 Analyses of p-MHC characteristics

## 581 2.2.4.1 UV-mediated peptide exchange assays

582 Biotinylated HLA-B\*07:02 monomers in complex with the UV-sensitive  
583 AARG(J)TLAM peptide were kindly provided by Stefan Stevanović (Tübingen, Ger-  
584 many). The UV-mediated peptide exchange was done as previously described [100] with  
585 slight modifications: The peptide exchange was performed using a concentration of  
586 0.025 µg/µl UV-sensitive monomers in a final volume of 125 µl PBS per well of a poly-  
587 propylene *MicroAmp*<sup>TM</sup> *Optical* 96-well reaction plate (Thermo Fisher Scientific).  
588 Graded amounts of the peptide of interest were added to the reaction wells with a final  
589 concentration ranging from 0.1 µM up to 200 µM in triplicates. As controls, conditions  
590 without peptide of interest (0 µM) and UV-irradiation were used. The 96-well reaction  
591 plate was stored on ice under a UV hand lamp (Köhler Technische Produkte) for 60' min  
592 with a distance between the plate and the UV hand lamp of approximately 5 cm. The UV  
593 wavelength was set to 365 nm. After irradiation, the plate was centrifuged for 5' min at  
594 3000 x g at 4°C and 100 µl supernatant of each well transferred to a new 96-well reaction  
595 plate and if necessary, stored covered with a sealing foil at -80°C.

## 596 2.2.4.2 Beta-2-microglobulin ELISA for Determination of HLA-stability

597 *Nunc-Immuno*<sup>TM</sup> *MicroWell*<sup>TM</sup> *Max-iSorp*<sup>TM</sup> flat bottom 96-well plates were coated with  
598 Streptavidin at a final concentration of 3 µg/ml in PBS and incubated for 2 h at 37°C.  
599 After four washing steps with PBS supplemented with 0.05% *Tween20* the plates were  
600 blocked for 30' min at RT with 300 µl 1% BSA/PBS. The blocking solution was dis-  
601 carded by flicking the plates, and without an additional washing step, 100 µl of a 1:10  
602 (PBS) dilution of the supernatant of UV-peptide exchanged HLA-B\*07:02 complexes  
603 (see chapter 2.2.4.1) was transferred to each well. The plates were incubated for 1 h at  
604 37°C covered with a sealing foil followed by four washing steps. Subsequently, the wells  
605 were incubated with 100 µl anti-beta-2-microglobuline antibody conjugated to HRP

606 (horseradish peroxidase) at a final concentration of 4  $\mu\text{g/ml}$  in 1% BSA/PBS for 1 h at  
607 37°C in the dark and covered with sealing foil. After the final four washing steps 100  $\mu\text{l}$   
608 of *OptEIA<sup>TM</sup> TMB substrate reagent* (BD) was added to the wells and incubated for  
609 10' min. The reaction was stopped by pipetting 50  $\mu\text{l}$  of sulfuric acid. The plates were  
610 measured with a Tecan Sunrise photometer using the Magellan software, setting the ab-  
611 sorbance to 450 nm and the reference channel to 570 nm.

#### 612 2.2.4.3 Differential Scanning Fluorimetry (Thermal shift assay)

613 For further determination of MPO-peptide-MHC stability, the Differential Scanning Flu-  
614 orimetry was performed for UV-exchanged MPO<sub>2</sub>- MPO<sub>2</sub>+L1-, MPO<sub>5</sub>- and as a control  
615 for pp65(417-426)-HLA-B7 complexes (see chapter 2.2.4.1). This technique was either  
616 used to measure the thermal stability with increasing temperature or the dissociation half-  
617 life of the peptides at constant physiological temperature (37°C). The p-MHC complexes  
618 were pipetted in MicroAmpR Fast Optical 96-well reaction plates (Applied Biosystems)  
619 in a final volume of 20  $\mu\text{l}$  containing 10 mM HEPES (pH 7.4), 150 mM NaCl, 3 mM  
620 EDTA, 2  $\mu\text{M}$  of UV-exchanged p-MHC-complexes and 10x SYPRO orange dye (Thermo  
621 Fisher Scientific). Afterward, the reaction plate was sealed with a film, and the samples  
622 were analyzed using a StepOnePlus RT-PCR instrument (Applied Biosystems, Foster  
623 City, USA). For thermal stability, a two-step melt curve analysis was selected, and a scan  
624 rate for the temperature of 1°C/min ranging from 20°C to 95°C was chosen. Step one:  
625 percentage ramp rate, start temperature = 20°C and time = 2' min. Step two: Endpoint  
626 temperature = 95°C, time = 2' min, melt curve = 1.0 and data were collected as well as on  
627 ramp and hold. For dissociation measurements, the setup was as follows: Melt curve  
628 stage: 100% ramp rate, 37°C, time = 00:15 data collection on the ramp and hold. Cycling  
629 stage: 160 cycles, 37°C, time = 05:00 and again data collection on the ramp and hold. The  
630 thermal stability analysis was performed as described elsewhere [101]. In brief, the rec-  
631 orded multicomponent data were exported to the Microsoft Excel-based *DSF Analysis*

632 *tool* (v3.0.2) available under the following link: (<ftp://ftp.sgc.ox.ac.uk/pub/biophysics>).

633 The tool provided processed data that were exported to GraphPad Prism (version 7.04,  
634 San Diego, USA) to fit them against Boltzmann equations to calculate the half-maximal  
635 temperature where p-MHC-complexes are denaturated ( $V_{50}$ ). For the calculating of the  
636 slowest dissociation rate of each p-MHC complex at 37°C, the multicomponent data set  
637 was used to plot the curves followed by a fit using a two-phase decay algorithm of  
638 GraphPad Prism (version 7.04, San Diego, USA).

#### 639 2.2.4.4 Molecular modeling of p-MHC complexes

640 The in-silico modeling of MPO-HLA-B7 complexes was kindly done by Manuel Glaser  
641 and Iris Antes from the Center for Integrated Protein Science at the Technical University  
642 Munich in Freising, Germany. A detailed description of experimental procedure and re-  
643 sults can be found in the PhD-thesis related publication [102].

#### 644 2.2.4.5 Immunopeptidomics

645 The purification and identification of HLA-I MPO-peptides were performed using LC-  
646 MS/MS analysis and was kindly done by Matteo Pecoraro at the Max Planck Institute of  
647 Biochemistry in Munich. For quantification of MPO-peptides using mass spectrometry,  
648 heavy labeled versions of the peptides were synthesized and spiked into the samples for  
649 coinstantaneous detection and ratio-based calculation of wildtype peptide levels. A de-  
650 tailed description of the method and the immunopeptidomics workflow was published  
651 previously [39].

### 652 2.2.5 FACS (Fluorescence-Activated Cell Sorting)

#### 653 2.2.5.1 Surface staining

654 Cells were washed with FACS buffer and blocked with  $\Delta$ HS for 20' min at 4°C followed  
655 by an additional washing step. In case of ex vivo isolated cells from mouse models, the  
656 cells were simultaneously blocked with anti-mouse CD16/32 antibody (1  $\mu$ g per million

657 cells in 100  $\mu$ l) and if necessary, before the blocking treated with ACK lysis buffer (Ther-  
658 moFisher Scientific) according to the manufacturer's instructions. Following this, the  
659 cells were re-suspended in FACS buffer and stained for surface markers and 7-AAD for  
660 live/dead discrimination for 30' min at 4°C in the dark. If not otherwise stated, the final  
661 concentrations of antibodies and 7-AAD was chosen according to the manufacturer's rec-  
662 ommendations. Afterward, the cells were washed with FACS-buffer, re-suspended in 2%  
663 fixation buffer and stored at 4°C in the dark until measurement.

#### 664 2.2.5.2 Intracellular staining

665 The intracellular staining was used to characterize the expression quality of different T-  
666 cell receptors. Therefore, the T cells were blocked with human serum added with ethidium  
667 monoazide bromide (EMA) at a final concentration of 1:500 for 10' min on ice in the  
668 dark. Following this, the samples were exposed to glaring light on ice for additional 10'  
669 min to bind the EMA label during the photolysis reaction covalently to the DNA of cells  
670 with compromised cell- and core membranes. After EMA-staining, the cells were washed  
671 in FACS-buffer followed by surface antibody staining (see chapter 2.2.5.1), and after an  
672 additional washing step with FACS-buffer, the cells were fixed with IC fixation buffer  
673 (eBioscience) for 20' min on ice in the dark. After fixation, the cells were washed twice  
674 with 1x permeabilization (eBioscience) buffer. Subsequently, the cells were stained for  
675 intracellular targets according to the manufacturer's recommendations for 20' min on ice  
676 protected from light. Finally, the cells were washed with 1x permeabilization buffer and  
677 once more with FACS-buffer containing 0.1% sodium azide before the cells were sus-  
678 pended in the same buffer for analysis by flow cytometry.

#### 679 2.2.5.3 Tetramer staining

680 For tetramer staining, the cells were blocked with human serum for 20' min on ice fol-  
681 lowed by a washing step with FACS-buffer. The tetramers were prepared for staining by  
682 centrifugation of the aliquot at 14.000g for 5' min to pellet possible aggregations. The

683 required amount of tetramer-supernatant was pipetted to PBS supplemented with 2mM  
684 EDTA and 50% FCS to meet a final concentration of tetramers in the sample of 30 µg/ml.  
685 The staining protocol follows the basic surface staining protocol described above (see  
686 chapter 2.2.5.1) with one exception. If the samples are co-stained with an antibody, the  
687 antibodies were pipetted 20' min later to the samples to ensure the correct binding of  
688 tetramers.

#### 689 2.2.5.4 Multi-cytokine analyses

690 For analyzation of human cytokines released by TCR-transduced T-Lymphocytes, the  
691 MACSPlex human Cytokine 12 Kit from Miltenyi Biotec (Bergisch Gladbach, Germany)  
692 was used. Sample preparation and data acquisition were performed according to manu-  
693 facturer guidelines. In brief, The MPx Cytokine 12 standard was gently mixed with 200  
694 µl TCM to obtain a concentration of 10 ng/ml. This stock solution was used to produce a  
695 standard of six levels by serial 1:5 dilutions comprising 2.000 pg/mL, 400 pg/mL, 80  
696 pg/mL, 16 pg/mL, 3.2 pg/mL and 0 pg/ml in TCM. The samples were prepared at room  
697 temperature and protected from light by centrifugation for 10' min at 10.000xg. In the  
698 meantime, the filter of the MACSPlex filter plate was pre-wetted with 200 µl MACSPlex  
699 buffer followed by centrifugation on top of a 96-flat-bottom plate for 3' min at 300xg and  
700 room temperature. Subsequently, 50 µl of standard and samples were transferred to the  
701 plate and mixed with 20µl of thoroughly vortexed capture beads for 2 h protected from  
702 the light on an orbital shaker at 450 rpm. The incubation was stopped by centrifugation  
703 for 3' min at 300xg followed by two washing steps with 200 µl MACSPlex buffer per  
704 well using the same centrifugation protocol. The filter bound beads were resuspended  
705 with 80 µl MACSPlex buffer and 20 µl detection reagent followed by another 1 h incu-  
706 bation protected from the light on an orbital shaker at 450 rpm. After the incubation, the  
707 samples were again centrifuged and washed as described above. Finally, the samples were  
708 resuspended in 200 µl MACSPlex buffer supplemented with 2% PFA and stored at 4°C

709 until FACS-based data acquisition. The data acquisition followed exactly the general in-  
710 structions for MACSPlex Cytokine Kits data acquisition and analysis without the  
711 MACSQuant® Analyzer from Miltenyi Biotec.

## 712 3 Results

## 713 3.1 Selection of tumor-associated antigens

714 The Myeloperoxidase (MPO)-derived peptides MPO<sub>67</sub>, MPO<sub>145</sub>, MPO<sub>360</sub>, MPO<sub>368</sub>, and  
 715 MPO<sub>466</sub> were identified by immunopeptidomics as previously described [43]. All exam-  
 716 ined MPO peptides within this work are restricted to HLA class I and described as poten-  
 717 tial therapeutic targets for cell-based immunotherapies [43]. Thereby, the MPO protein is  
 718 highly overexpressed in several patients' derived MPN and AML samples compared to  
 719 PBMC reference material [43]. The MPO-peptides MPO<sub>266</sub>, MPO<sub>357</sub>, and MPO<sub>603</sub> were  
 720 identified elsewhere [44]. Another fourteen MPO-peptides (Table 27) have been identi-  
 721 fied by immunopeptidomics within this work either on the APL or AML-derived tumor  
 722 cell lines NB4, HL60 and ML2 with transgenic HLA-B7 expression or on the SiG-M5  
 723 cell line with endogenous HLA-B7 expression. The immunopeptidomics approach was  
 724 kindly performed by Matteo Pecoraro at the Max Planck Institute of Biochemistry in  
 725 Martinsried, Germany.

726 **Table 27: NetMHC predicted affinities and Syfpeithi scores of MPO-derived peptides**

Peptide numbering derived from Isoform H7 (UniProtKB - P05164-3 (PERM_HUMAN))					NetMHC 4.0 [67, 103]	Syfpeithi [104]
Peptide	Source	Sequence	Restriction	Sample Type	Affinity (nM)	Score
MPO049		AAPAVLGEVDT (11mer)	possible HLA restriction: A*24:02, A*01:01, B*07:02, B*51:01	SiG-M5	for all HLAs very high	-

n.a. = not available. Peptides without reference are identified within this work.

### 727 3.1.1 Immunogenicity evaluation of possible target peptides using single HLA- 728 mismatched stimulations

729 The MPO-peptides identified by immunopeptidomics were restricted to different HLA  
730 class I molecules (Table 27) and were used to prime naïve CD8<sup>+</sup> T cells negative for the  
731 respective HLA-allele in a sHLAm setting. For that, autologous dendritic cells (DC) were  
732 electroporated with in-vitro transcribed (ivt)-RNA coding for the restriction element cou-  
733 pled to eGFP by a P2A element and pulsed with a peptide candidate before co-stimulation  
734 with the CD8<sup>+</sup> naïve T cells. Figure 1A exemplarily shows the phenotyping of mature DC  
735 and the electroporation efficiency of HLA-B\*07:02eGFP ivt-RNA assessed by flow cy-  
736 tometry using anti-CD83, -CD86 and -CD209 antibodies as well as eGFP, respectively.  
737 The DC data set shows a very high maturation phenotype with 98% of CD83 and CD86  
738 double positive DC with ~89% of CD209 expression. Compared to the non-electro-  
739 porated control, ~82% of the ivt-RNA electroporated DC express HLA-B7eGFP. After-  
740 wards, these DC were pulsed with respective peptides of interest and subsequently used  
741 to expand autologous HLA-B7<sup>-</sup> naïve CD8<sup>+</sup> T cells that were stimulated by the respective  
742 HLA-B7-peptide complex presented on the surface of the DC. Figure 1B graphically  
743 summarizes the sHLAm stimulation approach for the expansion of target antigen-respon-  
744 sive T cells with mature DCs.

745

748 **Figure 1: Phenotyping of matured Dendritic Cells (DC) and single HLA-mismatched stimulation.**  
 749 **(A) DC phenotyping using the marker CD83, CD86 and CD209 and eGFP for HLA-B7 expression.**  
 750 **(B) Expansion of peptide-specific CD8<sup>+</sup> T cells using sHLAm DC followed by T-cell enrichment and**  
 751 **cloning after fluorescence-activated cell sorting (FACS).**

### 752 3.2 Isolation of MPO-specific TCRs

753 For the identification of MPO-peptide specific T cells, HLA-multimer<sup>+</sup> CD8<sup>+</sup> T cells  
 754 stimulated in the sHLAm setting were sorted by flow cytometry. Subsequent clonal ex-  
 755 pansion followed by evaluation of their reactivity against either T2, K562 or C1R tumor  
 756 cell lines with transgenic-HLA expression was applied to select T-cell lines with reactiv-  
 757 ity against these target cell lines.

758 3.2.1 Identification of MPO<sub>145</sub>-, MPO<sub>368</sub>- and MPO<sub>603</sub>-specific T-cells

759 In the case of MPO<sub>145</sub>-stimulated T-cells a CD137<sup>+</sup> depletion step before HLA-multimer  
 760 sort was performed to reduce the proportion of T cells with an HLA-B7 reactivity that is  
 761 independent of the MPO<sub>145</sub> peptide. Therefore, the CD8<sup>+</sup> T cells, that had been stimulated  
 762 with the HLA-B7 restricted MPO<sub>145</sub>-peptide in the sHLAm approach were stimulated  
 763 with the lethally irradiated C1R-B7 tumor cell line. As those cells do not express MPO,  
 764 cells with a reactivity against HLA-B7 that is independent of MPO<sub>145</sub> were activated and  
 765 upregulated CD137. Those cells were depleted and the population of unspecific HLA-B7  
 766 alloreactive T cells was reduced from ~22% to ~3% (Figure 2).

767

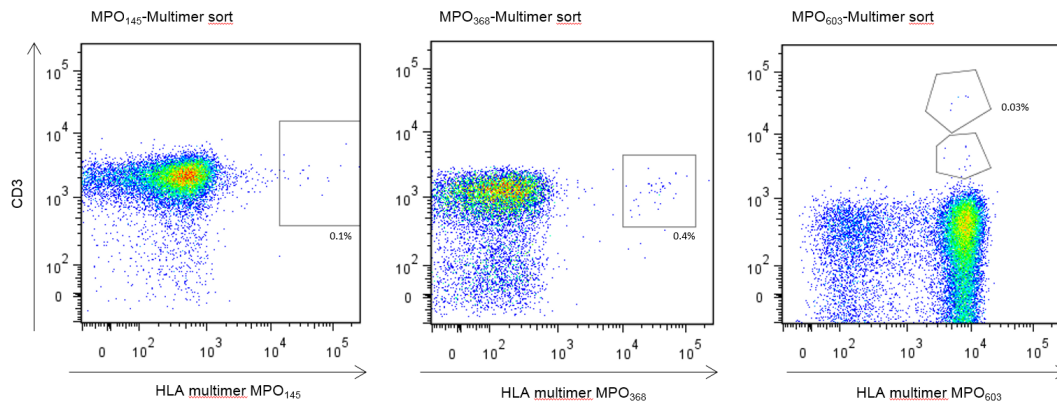

768

769 **Figure 2: Depletion of CD137<sup>+</sup> alloreactive T cells. Co-cultivation of T cells with lethally irradiated**  
 770 **HLA-B7-transgenic C1R cells in order to stimulate transient expression of the activation marker**  
 771 **CD137 used for flow cytometry-based depletion of CD137<sup>+</sup> T cells. Proportions of 7-AAD<sup>-</sup>**  
 772 **/CD137<sup>+</sup>/CD3<sup>+</sup> T cells are shown before and after depletion of CD137<sup>+</sup> T cells.**

773 After the reduction of potential alloreactive T cells, the remaining MPO<sub>145</sub>-stimulated  
 774 T cells were sorted by MPO<sub>145</sub>-HLA-multimer. The MPO<sub>368</sub>- and MPO<sub>603</sub>-stimulated  
 775 T cells were sorted accordingly. A proportion of 0.1% of all T cells used for sorting was  
 776 positive for the MPO<sub>145</sub>-HLA-multimer, 0.4% for the MPO<sub>368</sub>-HLA-multimer, and 0.03%  
 777 for the MPO<sub>603</sub>-HLA-multimer (Figure 3). The results of initially evaluated peptide-spec-  
 778 ificity of the MPO<sub>368</sub>- and MPO<sub>603</sub>-peptide-stimulated T-cell lines were promising (Fig-  
 779 ure 4) and sorted populations were additionally cloned by limiting dilutions. The cultured

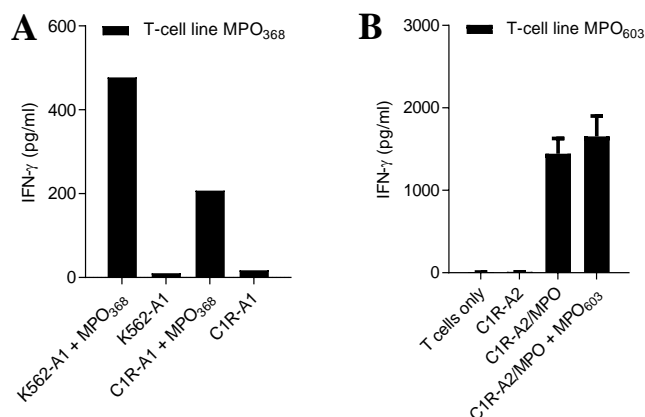

780 T-cell line of the MPO<sub>145</sub> approach did not expand sufficiently and was lost. Therefore,  
 781 no results for the peptide specificity of the MPO<sub>145</sub>-T-cell line are available.

782

783 **Figure 3: MPO-HLA-multimer sort of T cells. Staining and multimer sort of MPO<sub>145</sub>-, MPO<sub>368</sub>- and**  
 784 **MPO<sub>603</sub>-stimulated T cells were done using the HLA-multimer technology. Cells were pre-selected**  
 785 **on propidium iodide negative events.**

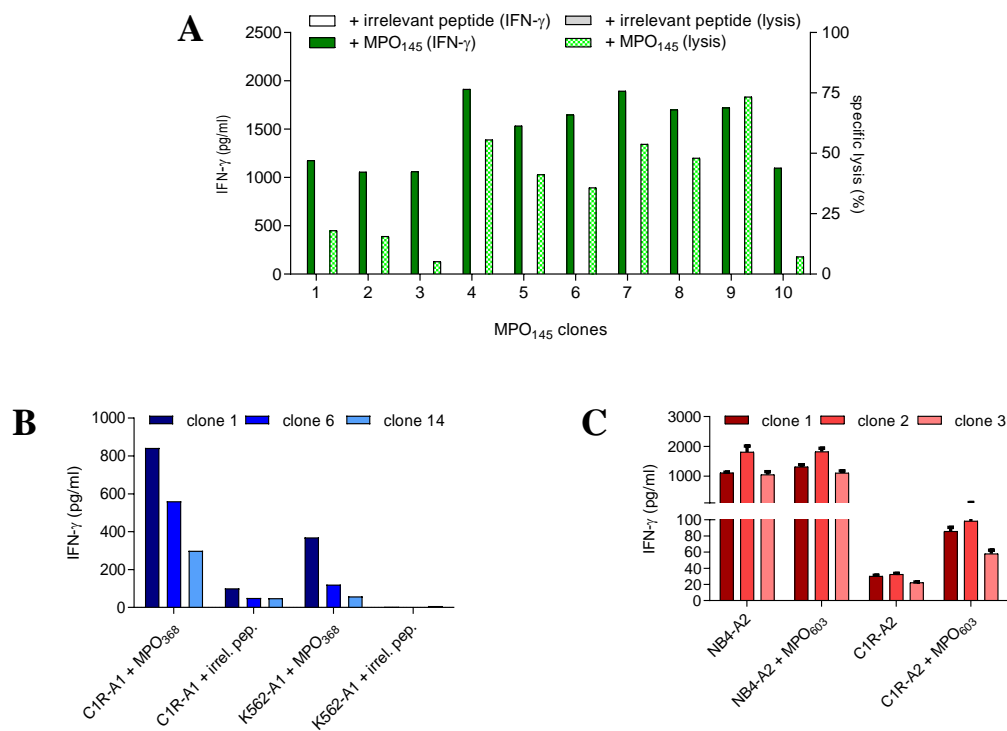

786 For MPO<sub>368</sub> (HLA-A1) and MPO<sub>603</sub> (HLA-A2), however, T-cell line expansion was suc-  
 787 cessful and T cells displayed both reactivity and peptide specificity against K562/C1R-  
 788 A1 or C1R-A2 target cells pulsed with the respective MPO-peptide or transduced with a  
 789 vector coding for the whole MPO protein (Figure 4).

790 **Figure 4: IFN- $\gamma$  release of T-cell lines against peptide-pulsed or antigen-transduced target cell lines.**  
 791 **(A): T-cell line MPO<sub>368</sub> stimulated with K562-A1 or C1R-A1 target cells either pulsed with MPO<sub>368</sub>**  
 792 **or not. (B): T-cell line MPO<sub>603</sub> stimulated with C1R-A2 target cells either pulsed with MPO<sub>603</sub>, trans-**  
 793 **duced with the whole MPO-antigen (MPO) or without expression of the antigen. T-cell responses**  
 794 **were analyzed by IFN- $\gamma$  ELISA.**

795 Figure 5 shows the results of MPO<sub>368</sub>-, MPO<sub>603</sub>- and MPO<sub>145</sub>-peptide-specific T-cell  
796 clones evaluated by either IFN- $\gamma$  production after stimulation with and/or cytotoxicity  
797 against the HLA-B7-transgenic tumor cell lines K562-A1, K562-B7, C1R-A1, C1R-A2  
798 or NB4-A2. For MPO<sub>145</sub> all tested T-cell clones showed peptide-specific reactivity  
799 against the MPO<sub>145</sub>-pulsed K562-B7 cell line (Figure 5A). Three examined T-cells clones  
800 of the MPO<sub>368</sub>-condition showed peptide specificity against the MPO<sub>368</sub>-pulsed tumor cell  
801 lines C1R-A1 and K562-A1 (Figure 5B). For the MPO<sub>603</sub>-condition, a clear peptide-spe-  
802 cific T-cell response could be observed against the tested C1R-A2 cell line pulsed with  
803 the MPO<sub>603</sub>-peptide. NB4-A2 cells express MPO endogenously and were recognized  
804 without pulsing with the MPO<sub>603</sub> peptide. The reactivity against the NB4-A2 cell line  
805 after MPO<sub>603</sub>-peptide pulsing showed no beneficial effect on the T-cell response (Figure  
806 5C). This might be related to the already sufficient endogenous presentation of MPO<sub>603</sub>  
807 on HLA-A2 complexes.

808

809 **Figure 5: MPO-peptide specificity of T-cell clones.** T-cell clones were assessed for peptide specificity  
 810 against peptide-pulsed target cells. (A) MPO<sub>145</sub> T-cell clones directed against K562-A1 target cells  
 811 either pulsed with MPO<sub>145</sub> or an irrelevant peptide. (B) MPO<sub>368</sub> T-cell clones directed against C1R-  
 812 A1 or K562-A1 target cells either pulsed with MPO<sub>368</sub> or an irrelevant peptide. (C) MPO<sub>603</sub> T-cell  
 813 clones directed against NB4-A2 or C1R-A2 target cells either pulsed with MPO<sub>603</sub> or without peptide  
 814 pulsing. (A-C): IFN- $\gamma$  release was analyzed by IFN- $\gamma$  ELISA and peptide-specific lysis of target cells  
 815 by flow cytometry at an effector to target ratio of approximately 20:1.

### 816 3.2.2 Isolation of MPO<sub>145</sub>-, MPO<sub>368</sub>- and MPO<sub>603</sub>-specific TCRs

817 For the identification of the TCR sequences of MPO<sub>145</sub>-, MPO<sub>368</sub>- and MPO<sub>603</sub>-specific  
 818 T cells, T-cell repertoires were analyzed by PCR and gel electrophoresis using cDNA  
 819 extracted from specific T-cell clones as starting material. Specific PCR products besides  
 820 the amplified controls were extracted from the gel, and the sequences including the CDR3  
 821 regions were identified by sequencing (Table 28). As a representative result for all three  
 822 TCRs, the TCR- $\alpha$  and TCR- $\beta$  repertoire of the MPO<sub>145</sub>-TCR is shown in Figure 6.

823 **Table 28: Variable  $\alpha$ - and  $\beta$ -chains of MPO<sub>145</sub>-, MPO<sub>368</sub>- and MPO<sub>603</sub>-TCR**

---

<b>TCR</b>	<b>variable <math>\alpha</math>-chain + CDR3</b>	<b>variable <math>\beta</math>-chain + CDR3</b>
<b>MPO<sub>145</sub>-TCR</b>	Va2 - CAVVSGGYQKVTF	Vb1 - CASSVVRSTDTQYF
<b>MPO<sub>368</sub>-TCR</b>	Va1 - CAVTGGGNKLTf	Vb21 - CASSWDNSYEQYF

 828 **products for the Primer Va2 and Va4 (A) as well as for Vb1(B). The PCR product for Va4 was identified as an unproductive TCR rearranged sequence. M = marker, Number = either variable  $\alpha$ - or  $\beta$ -**  
 829 **Primer used for amplification.**  
 830

831 3.2.3 Transfer of TCR specific for MPO<sub>145</sub>, MPO<sub>368</sub>, and MPO<sub>603</sub> to recipient T cells

832 To be able to use TCRs in adoptive T-cell therapies using TCR-transgenic T cells, it is  
 833 necessary to transfer the TCRs to recipient T-lymphocytes. To additionally enhance TCR  
 834 expression and reduce mispairing of transgenic with endogenous TCR chains in recipient  
 835 cells, codon optimized and murinized versions of the  $\alpha$ - and  $\beta$ -chains of the MPO<sub>145</sub>-,  
 836 MPO<sub>368</sub>- and the MPO<sub>603</sub>-TCR were synthesized, cloned into the retroviral vector MP71

837 and retrovirally transduced into healthy donor T-lymphocytes. The results in Figure 7  
 838 show representatively, that all three TCRs differ in their transduction efficiencies as de-  
 839 termined by FACS-based measurements using an anti-mouse TCR- $\beta$  chain antibody  
 840 (TCRm) specific for the murinized constant  $\beta$ -chain of all three TCRs. While the MPO<sub>145</sub>-  
 841 and the MPO<sub>368</sub>-TCR could be efficiently transferred, exemplarily shown for PBMCs  
 842 (Figure 7A, B, ~ 42%/63%), the MPO<sub>603</sub>-TCR displayed only minimal amounts of the  
 843 murinized TCR- $\beta$  chains after transduction (Figure 7C, ~ 5%). Intracellular staining for  
 844 the murinized TCR- $\beta$  chains in MPO<sub>603</sub>-TCR-transduced T cells revealed that the TCR  
 845 was almost completely trapped intracellularly (Figure 8). Because of this insufficient sur-  
 846 face expression, the characterization of the MPO<sub>603</sub>-TCR had to be discontinued.

847

848 **Figure 7: Transduction efficacies of the MPO<sub>145</sub>-, MPO<sub>368</sub>- and MPO<sub>603</sub>-TCR. Flow cytometry**  
 849 **analysis of 7-AAD<sup>-</sup> TCR-transduced healthy donor lymphocytes. (A): MPO<sub>145</sub>-TCR. (B): MPO<sub>368</sub>-**  
 850 **TCR. (C): MPO<sub>603</sub>-TCR.**

851

852 **Figure 8: Intracellular TCRm staining of the MPO<sub>603</sub>-TCR. Flow cytometry analysis of EMA<sup>+</sup> TCR-**  
853 **transduced healthy donor lymphocytes.**

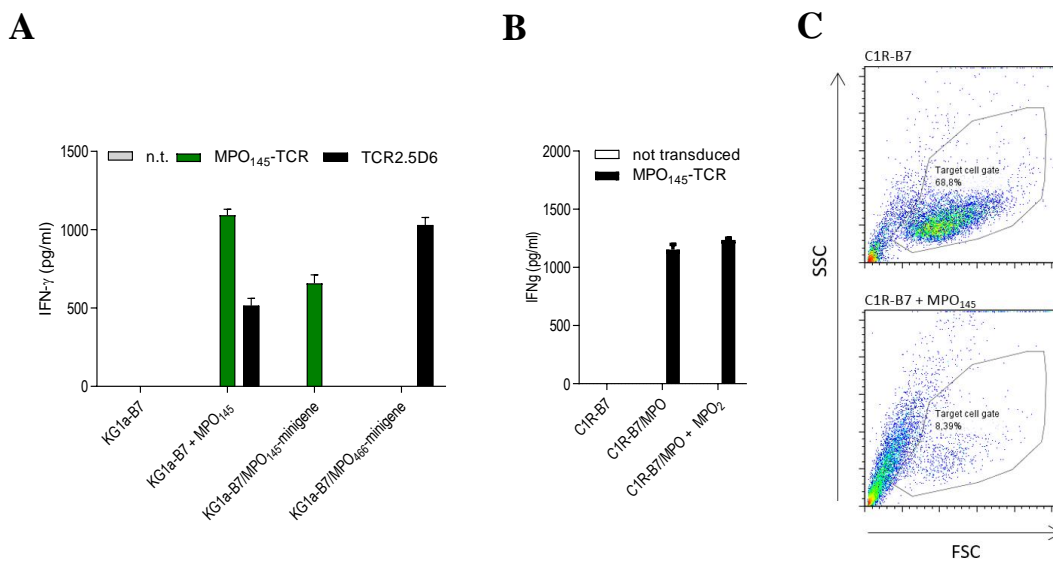

854 After successful transduction of the MPO<sub>145</sub>- and MPO<sub>368</sub>-TCR in T cells, peptide speci-  
855 ficity and cytotoxic potential of the TCR-transgenic T-cell lines were tested. Surprisingly,  
856 the MPO<sub>368</sub>-TCR with HLA-A1 restriction recognized the HLA-B7 transgenic and MPO<sup>+</sup>  
857 tumor cell line NB4 that does not express HLA-A1 (Figure 9). The recognition of the  
858 MPO<sup>+</sup> HL60-B7 cell line, however, was expected because of endogenous expression of  
859 HLA-A1 that is absent in the tested NB4 cell line. As the MPO<sub>368</sub>-independent recogni-  
860 tion of HLA-B7-transgenic NB4 cells has been observed in several experiments, the char-  
861 acterization of the MPO<sub>368</sub>-TCR was discontinued.

862 The MPO<sub>145</sub>-TCR-transduced T cells specifically recognized MPO<sub>145</sub>-pulsed or MPO<sub>145</sub>-  
863 minigene transduced KG-1a (Figure 10A) as well as C1R transgenic for the MPO protein  
864 (Figure 10B) with the correct restriction element HLA-B7. Furthermore, MPO<sub>145</sub>-TCR-  
865 transduced T cells efficiently killed the NB4-B7 cell line with endogenous MPO-protein  
866 expression (Figure 10C).

867

868 **Figure 9: Missing MPO<sub>368</sub>-specificity of MPO<sub>368</sub>-TCR-transduced T cells.** The T-cell response of  
 869 MPO<sub>368</sub>-TCR-transduced T cells was analyzed by IFN-γ ELISA after co-cultivation with either the  
 870 MPO<sub>368</sub>-pulsed target cell lines NB4-B7, NB4-A1, HL60-A1 or HL60-B7 or without peptide pulsing.

871 **Figure 10: Peptide specificity of MPO<sub>145</sub>-TCR-transduced T cells.** (A, B): T-cell response of MPO<sub>145</sub>-  
 872 TCR-transduced T cells directed against the target cell lines KG-1a-B7 or C1R-B7 either pulsed with  
 873 the relevant MPO-peptide or transduced with the MPO-minigene (/MPO<sub>xxx</sub>-minigene) or the MPO-  
 874 protein sequence (/MPO). (C): Cytotoxicity of MPO<sub>145</sub>-TCR-transduced T cells against the C1R-B7  
 875 target cell line pulsed with MPO<sub>145</sub>. IFN-γ release was assessed by IFN-γ ELISA; Cytotoxicity was  
 876 assessed by measuring the number/percentage of 7-AAD<sup>-</sup>GFP<sup>+</sup> C1R-B7 target cells using flow cy-  
 877 tometry. TCR2.5D6 served as control for epitope-specific target recognition.

878 Taken together, the peptide-specific TCR reactivity of all three TCRs, observed at the  
 879 clonal T-cell level, could be successfully transferred to recipient-donor T cells for the  
 880 MPO<sub>145</sub>-TCR. This TCR is from now on named TCRF5.4.

881 3.2.4 Peptide-dependent and -independent cross-reactivity of TCRF5.4 against various  
882 HLA molecules

883 For further cross-reactivity analysis of the MPO<sub>145</sub>-TCR, the peptide-dependent and in-  
884 dependent cross-reactivity against a set of lymphoblastoid cell lines (LCL) were tested  
885 covering a broad variety of different HLA-alleles (Table 29). The LCLs were either  
886 pulsed with the MPO<sub>145</sub>-peptide or not and co-cultured with MPO<sub>145</sub>-TCR-transgenic  
887 T cells. The results (Figure 11) revealed MPO<sub>145</sub>-independent cross-reactivities against  
888 the RML- and LWAGS-LCLs expressing HLA-A02 and HLA-B51 or HLA-A33 and  
889 HLA-B14, respectively. The LCL cell lines MaOe, JNB3 and LSK1 served as positive  
890 controls after MPO<sub>145</sub>-peptide pulsing.

891 **Table 29: HLA-A\* and HLA-B\* phenotype of lymphoblastoid cell lines**

LCL cell line	HLA-A*	HLA-B*	LCL cell line	HLA-A*	HLA-B*
AMALA	02:17/ --	15:01/ --	LWAGS	33:01/ --	14:02/ --

893

894 **Figure 11: MPO<sub>145</sub>-dependent and -independent reactivity against a panel of lymphoblastoid cell**  
895 **lines. The T-cell response of MPO<sub>145</sub>-TCR-transduced T cells directed against various LCL target**  
896 **cell lines either pulsed with the MPO<sub>145</sub>-peptide or without peptide pulsing. IFN-γ release was as-**  
897 **essed by IFN-γ ELISA. HLA-expression of the LCL cell lines is shown in Table 29.**

898 In other experiments, the reactivity against a set of HLA-B7 restricted peptides pulsed in  
899 pools on C1R-B7 cells was tested. Here, no recognition of the tested peptides (list of  
900 peptide sequences and composition of pools is shown Table 30) by MPO<sub>145</sub>-TCR-trans-  
901 genic T cells could be observed (Figure 12). As controls, the C1R-B7 cell line pulsed with  
902 the MPO<sub>145</sub>-peptide (positive control) and not transduced T cells or target cells not pulsed  
903 with the MPO<sub>145</sub>-peptide (negative controls) were used.

## 911 3.2.5 Reactivity of TCRF5.4 against hematopoietic tumor cell lines

912 As the MPO<sub>145</sub>-TCR revealed a promising safety pattern, reproducible high transgenic  
913 expression in transduced T cells and peptide specificity, this TCR was characterized in  
914 more detail.

915 First, the reactivity against tumor cells of hematopoietic origin was tested using a set of  
 916 HLA-B7-transgenic tumor cell lines with or without endogenous MPO expression. As  
 917 controls MPO-negative target cell lines, not transduced T cells or PMA/IONO-stimulated  
 918 T cells were used. Only the target cell lines with the MPO<sub>145</sub>-restriction element, namely  
 919 HLA-B7, and endogenous MPO expression or pulsed with the MPO<sub>145</sub>-peptide were rec-  
 920 ognized by TCRF5.4-transgenic T cells (Figure 13). While all cell lines with exact re-  
 921 quirements were recognized reliably by TCRF5.4-transgenic T cells, substantial differ-  
 922 ences in quantitative responses could be observed between the different target cell lines.  
 923 However, except for target cell lines SET2-B7 and MOLT4-B7, the IFN- $\gamma$  response levels  
 924 towards all MPO<sub>145</sub>-pulsed target cell lines were similar. The observed differences in  
 925 IFN- $\gamma$  release upon stimulation with the target cell lines with endogenous MPO expres-  
 926 sion in comparison to their additionally MPO<sub>145</sub>-pulsed pendants, is an indication for lim-  
 927 ited saturation of HLA-B7 molecules on the cell surface with endogenously processed  
 928 MPO<sub>145</sub>-peptides which could be enhanced after additional MPO<sub>145</sub>-peptide pulsing.

929

930 **Figure 13: Reactivity of TCRF5.4-transduced T cells against target cell lines of hematopoietic origin.**  
 931 **The T-cell response of TCRF5.4-transduced T cells is shown against various cell lines of hematopoi-**  
 932 **etic origin with or without endogenous MPO expression either pulsed with the MPO<sub>145</sub>-peptide or**  
 933 **not. The T-cell response was analyzed by IFN- $\gamma$  ELISA.**

934 3.2.6 TCRF5.4 reactivity against primary cell material

935 To evaluate the reactivity of TCRF5.4-transduced T cells against primary tumor cells, a  
 936 panel of CML cell samples were used. CML 1, 2, 5, 13 and 15 are positive for both MPO  
 937 and HLA-B7 expression while CML 9 and 10 are negative for both markers and served  
 938 beside the C1R-B7 cell line as negative controls (Figure 14). The validation of MPO-  
 939 protein expression was evaluated by Richard Klar by immunopeptidomics, flow cytome-  
 940 try or qPCR [43]. TCRF5.4-transduced T cells showed reactivity against CML 2, 5, 13  
 941 and 15 without additional MPO<sub>145</sub>-peptide pulsing. CML 1 was only recognized after  
 942 additional MPO<sub>145</sub>-peptide pulsing indicating insufficient endogenous MPO<sub>145</sub>-HLA-B7-  
 943 epitope presentation on the surface of the cells. In general, the IFN- $\gamma$  release of TCRF5.4-  
 944 transduced T cells was higher after additional MPO<sub>145</sub>-peptide pulsing.

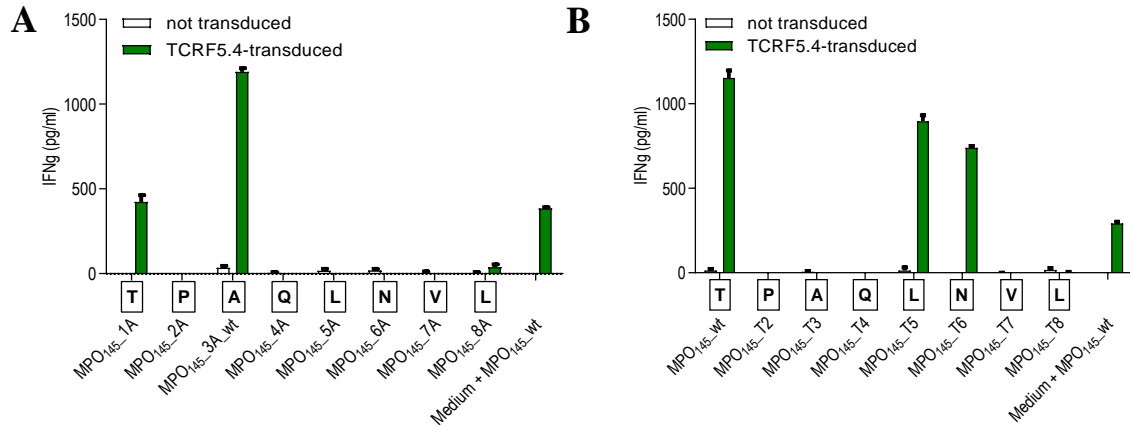

945

946 **Figure 14: Reactivity of TCRF5.4-transduced T cells against primary CML samples. The T-cell re-**  
 947 **sponse of TCRF5.4-transduced T cells is shown against primary CML cells either with or without**  
 948 **endogenous MPO expression and correct or missing HLA-B7 restriction. As a control, the target cell**  
 949 **lines were additionally pulsed with the MPO<sub>145</sub>-peptide. The T-cell response was analyzed by IFN- $\gamma$**   
 950 **ELISA.**

951 3.2.7 Amino acid substitution assays of the MPO<sub>145</sub>-peptide

952 For the identification of the most critical amino acids of the MPO<sub>145</sub>-peptide responsible  
 953 for the peptide specificity of TCRF5.4, amino acid exchange experiments were per-

954 formed. For that, each amino acid of MPO<sub>145</sub> was successively substituted by either ala-  
 955 nine or threonine (Figure 15 A, B). MPO-peptide variants were pulsed on the LCL cell  
 956 line MaOe with endogenous HLA-B7 expression. After co-cultivation with TCRF5.4-  
 957 transgenic T cells, secretion of IFN- $\gamma$  was analyzed, and the TCR-binding motifs of the  
 958 recognition patterns were assessed.

959

960 **Figure 15: Recognition of Alanine- or Threonine substituted MPO<sub>145</sub>-peptide variants. The T-cell**  
 961 **response of TCRF5.4-transduced T cells is shown against the LCL target cell line (MaOe) pulsed**  
 962 **with either Alanine- (A) or Threonine- (B) substituted MPO<sub>145</sub>-peptide variants. T-cell responses**  
 963 **were assessed by IFN- $\gamma$  ELISA.**

964 Using the ScanProsite tool [92], alanine substitutions resulted in the binding motif *X-P-*  
 965 *A-Q-L-N-V-X* with no hit outside the MPO source protein. The threonine variant coun-  
 966 terparts led to the motif *T-P-A-Q-X-X-V-L* with one hit in the human proteome outside  
 967 the MPO source protein. Taken together, the amino acid substitutions using alanine and  
 968 threonine revealed different TCR recognition motifs. The combination of both patterns  
 969 resulting in the motif *X-P-A-Q-X-X-V-X* generates numerous hits (297) outside the MPO  
 970 source protein. This result would indicate highly critical peptide promiscuity.

### 971 3.3 Functional characterization of TCRF5.4 compared to TCR2.5D6

972 The MPO<sub>466</sub>-peptide-specific TCR named TCR2.5D6 with HLA-B7 restriction was char-  
973 acterized in-depth previously [43]. To broaden the understanding of TCR-mediated  
974 recognition and evaluation of characteristics that are essential for TCR's successful clin-  
975 ical translation, TCR2.5D6 was selected for detailed comparison with the novel TCRF5.4.  
976 Both TCR share the same restriction element, but target different peptides derived from  
977 the same MPO antigen.

#### 978 3.3.1 Comparison of TCR transduction efficiency and surface expression

979 The mean transduction efficiency for TCRF5.4 (72.2%) was approximately 10% lower  
980 compared to TCR2.5D6 (84.5%) (Figure 16A). Although this holds true for nearly all  
981 examined healthy donor T cells, partly substantial differences could be observed between  
982 different donors used for transduction. An even stronger effect was observed for the TCR-  
983 surface expression (mean fluorescens intensity, MFI) analyzed by flow cytometry using  
984 the anti-mouse TCR- $\beta$  chain (TCRm) antibody. Here, the TCR2.5D6 showed considera-  
985 bly enhanced TCR surface density compared to TCRF5.4 (Figure 16B). Additional stain-  
986 ing for residual intracellular TCRs revealed that a part of the TCRF5.4 is kept inside the  
987 T cells while the TCR2.5D6 is completely located on the surface of the T cells (Figure  
988 17). Summarized, the TCRF5.4 could not compete with the TCR2.5D6 regarding trans-  
989 duction efficacy, surface expression as well as surface density.

990

991 **Figure 16: Transduction efficiency and mean fluorescence intensity of TCRF5.4 compared to**  
 992 **TCR2.5D6. (A): murine TCR- $\beta$  chain transduction efficiency of CD3<sup>+</sup>7-AAD<sup>-</sup> T cells; (B): Mean flu-**  
 993 **orescence intensity of the murine TCR- $\beta$  chain of T cells analyzed in (A).**

994

 996 **presentation of the murine TCR- $\beta$  chain (TCRm) of TCR2.5D6- or TCRF5.4-transduced T cells. The**  
 997 **cells were pre-gated for EMA<sup>-</sup>CD3<sup>+</sup> events.**

### 998 3.3.2 Comparison of functional avidity

999 To test the functional avidity, the KG-1a and the C1R target cell lines without endogenous  
 1000 MPO but transgenic HLA-B7 expression were used. The target cells were pulsed with  
 1001 graded amounts of either MPO<sub>145</sub> or MPO<sub>466</sub> and co-incubated with TCRF5.4- or  
 1002 TCR2.5D6-transduced T cells, respectively. The calculation of half maximal response  
 1003 (EC<sub>50</sub>) of the transduced T cells after stimulation was used as a basis to determine the  
 1004 TCR's functional avidity. Of note, for this comparison both TCR-transduced T cells were  
 1005 neither adjusted to TCR-expression nor to TCR-transduction efficiency in order to char-

1006 acterize both TCRs with their limitations. The results revealed highly comparable func-  
1007 tional avidity values for both TCRs with a median of 40.89 nM for the TCRF5.4 and  
1008 46.15 nM for the TCR2.5D6 (Figure 18).

1009

1010 **Figure 18: Pooled results of functional avidity for TCRF5.4 and TCR2.56. Comparison of EC<sub>50</sub> values**  
1011 **of functional avidity assessed for both TCR-transduced T cells (n=8). The functional avidity was cal-**  
1012 **culated measuring the IFN- $\gamma$  release of TCR-transduced T cells stimulated with the KG-1a-B7 target**  
1013 **cell line pulsed with graded amounts of the relevant MPO-peptide and consecutive EC<sub>50</sub> determina-**  
1014 **tion using GraphPad Prism (version 8).**

1015 3.3.3 Comparison of dissociation rates of TCR-p-MHC-complex ( $K_{off}$ )

1016 For further characterization of TCR-p-MHC binding kinetics, the dissociation rate of the  
1017 p-MHC complexes from the TCR-transduced T cells was calculated. These  $k_{off}$ -measure-  
1018 ments were used to evaluate the half-life ( $t_{1/2}$ ) and subsequently to get an indication for  
1019 the stability of both complexes (Figure 19). Equivalent to the results of the functional  
1020 avidity, no significant differences could be observed for both TCRs displaying similar  $k_{off}$   
1021 values of a median of 70.7 s for TCRF5.4 and 64.6 s for TCR2.5D6.

1022

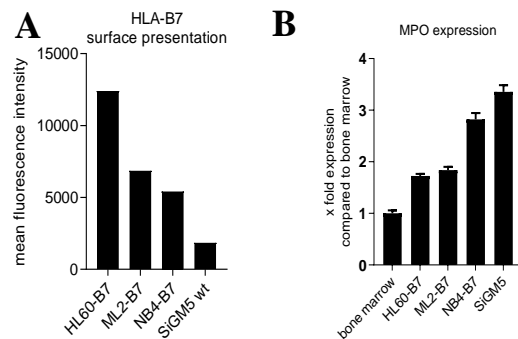

1023 **Figure 19: Dissociation rate of the MPO-peptide-MHC complexes from TCRF5.4- or TCR2.5D6-**  
1024 **transduced T cells ( $k_{off}$ ). Comparison of  $k_{off}$  of both TCR-transduced T cell populations (TCRF5.4,**  
1025 **n=4; TCR2.5D6, n=5). The signal decay of fluorescent labeled MPO-peptide-MHC complexes bound**  
1026 **to the T cells was monitored by flow cytometry of pre-gated CD3<sup>+</sup>PI<sup>-</sup> T cells over time.  $T_{1/2}$  was cal-**  
1027 **culated using GraphPad Prism's exponential decay algorithm [102].**

## 1028 3.3.4 Comparison of cytokine secretion patterns

1029 After the assessment of TCR-transduction qualities, TCR functional avidity and dissoci-  
1030 ation times of both TCR-p-MHC complexes, the quality and quantity of cytokine secre-  
1031 tion after stimulation of TCR-transduced donor T cells were analyzed using the AML cell  
1032 lines ML2, NB4, HL60 and SiG-M5. Common to all these cell lines is the endogenous  
1033 MPO expression. The cell lines ML2, NB4, and HL60 are transgenic for HLA-B7 while  
1034 the SiG-M5 cell line is endogenously expressing HLA-B7.

1035 Initially, the HLA-B7 expression of all cell lines was analyzed by flow cytometry. The  
1036 results indicated substantial differences in HLA-B7 expression levels between the differ-  
1037 ent AML-cell lines. The HL60 cell line displayed the highest expression of transgenic

1038 HLA-B7 whereas the SiG-M5 was the cell line with the lowest HLA-B7 expression (Fig-  
 1039 ure 20A). Additionally, the differences in the MPO-mRNA expression of the four AML  
 1040 cell lines were assessed using the SYBR-Green qPCR technique. The results were com-  
 1041 pared to the expression of MPO-mRNA of human bone marrow samples. Within all  
 1042 AML-cell lines, the SiG-M5 cell line showed the highest level of MPO-mRNA (3.4x)  
 1043 followed by NB4 (2.8x), ML2 (1.8x) and HL60 (1.7x) with the lowest mRNA expression  
 1044 (Figure 20B). Compared to the results of the HLA-B7 expression, the MPO expression is  
 1045 precisely the opposite. The HL60 cell line with the highest HLA-B7 surface density ex-  
 1046 pressed the lowest amounts of MPO-mRNA while the SiG-M5 cell line expressed the  
 1047 highest MPO-mRNA levels displayed the lowest HLA-B7 density on the surface of the  
 1048 cells. Therefore, the chosen set of AML-cell lines for the cytokine release characterization  
 1049 of TCR-transgenic T cells covers a broad range of possible HLA-B7- and MPO-expres-  
 1050 sions.

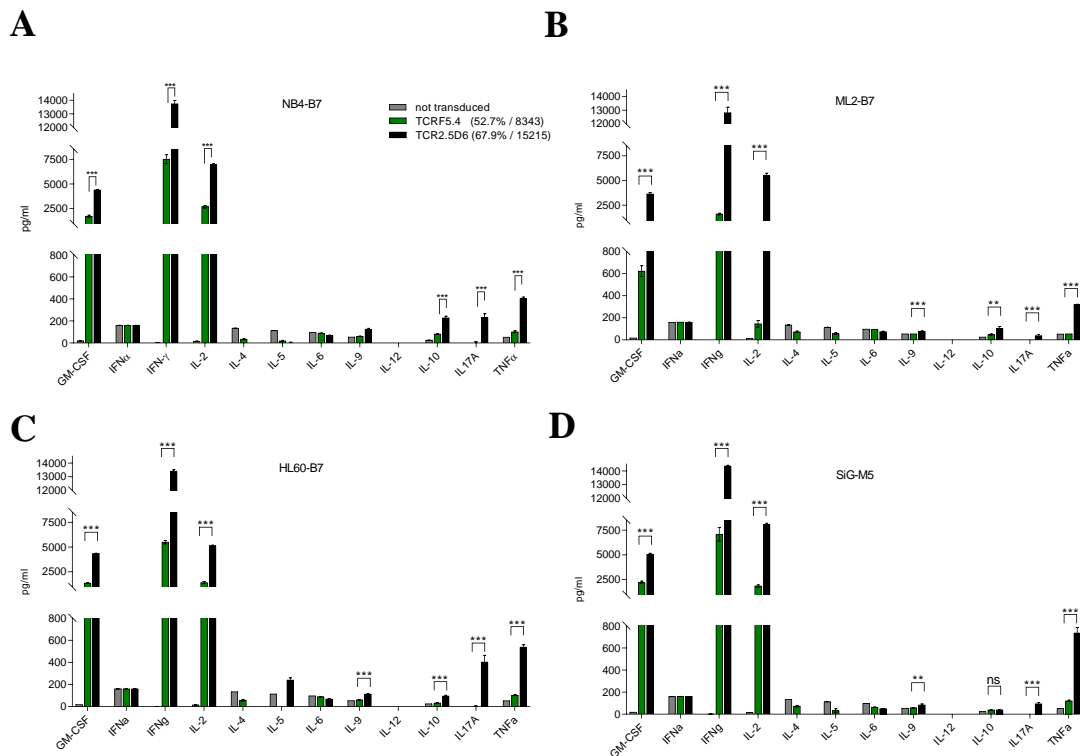

1051

1052 **Figure 20: Cell surface expression of HLA-B7 and mRNA expression of the MPO protein in AML**  
 1053 **cell lines. (A): Mean fluorescence intensity of transgenic HLA-B7 on the AML-cell lines HL60-B7,**  
 1054 **ML2-B7 and NB4-B7 as well as endogenous expressed HLA-B7 on the SiG-M5 cell line. (B): Semi-**  
 1055 **quantitative real-time PCR normalized to the genes GAPDH, HPRT1, and HMBS. The MPO expres-**  
 1056 **sion levels in the AML-cell lines HL60-B7, ML2-B7, NB4-B7, and SiG-M5 were compared to the**  
 1057 **expression in healthy bone marrow samples [102].**

1058 As a next step, the cytokine profile of TCRF5.4 and TCR2.5D6 transduced PBMC was  
 1059 assessed after co-incubation with AML-cell lines HL60-B7, ML2-B7, NB4-B7 and SiG-  
 1060 M5 comprising the following cytokines: GM-CSF, IFN $\alpha$ , IFN- $\gamma$ , IL-2, IL-4, IL-5, IL-6,  
 1061 IL-9, IL-12, IL-10, IL17A and TNF $\alpha$  (Figure 21 A-D).

1062

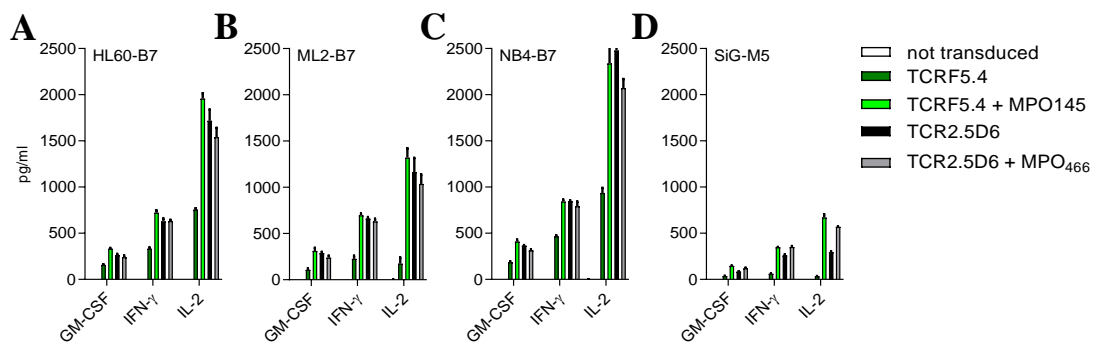

1063

1064 **Figure 21: Cytokine release of TCRF5.4- and TCR2.5D6-transduced T cells. Selected cytokines were**  
 1065 **analyzed by a multiplexed flow cytometry approach. The AML-cell lines NB4-B7 (A), ML2-B7 (B),**  
 1066 **HL60-B7 (C) and SiG-M5 (D) were co-incubated either with the TCRF5.4- or TCR2.5D6-trans-**  
 1067 **duced T cells for 20h and the supernatants used for the consecutive cytokine staining. The quantity**  
 1068 **of cytokines was calculated according to standard curves measured for each cytokine. The results**  
 1069 **were compared to a not transduced T-cell control. The results are shown in triplicates for n=2, \*\*p**  
 1070 **> 0.05, \*\*\*p > 0.001.**

1071 As shown before in previous co-stimulation experiments for the IFN- $\gamma$  release, differ-  
 1072 ences were also seen in the quantity of cytokine secretion for GM-CSF, IFN- $\gamma$  and IL-2  
 1073 between TCRF5.4 and TCR2.5D6. TCR2.5D6-transduced PBMCs significantly secreted  
 1074 higher amounts of cytokines compared to TCRF5.4-transduced PBMCs. Additionally,  
 1075 TCR2.5D6-transduced PBMCs secreted detectable amounts of IL-10, IL-17A and TNF $\alpha$

1076 compared to TCRF5.4-transduced PBMC with very low or even undetectable cytokine  
 1077 levels. Thus, besides quantitative differences in cytokine secretion, there is also a quali-  
 1078 tative difference between both TCR-transduced T cells.

1079 However, in repetition experiments using the same four AML-cell lines with additional  
 1080 exogenous peptide pulsing of 1  $\mu$ M MPO<sub>145</sub> or MPO<sub>466</sub>, the quantitative lower cytokine  
 1081 secretion observed for TCRF5.4-transduced T cells was compensated and similar to  
 1082 TCR2.5D6-transduced T cells (Figure 22). Interestingly, additional MPO<sub>466</sub>-peptide puls-  
 1083 ing showed a beneficial effect for SiG-M5 cells whereas the other AML-cell lines re-  
 1084 mained rather unaffected. This result is in line with the low HLA-B7 expression of the  
 1085 SiG-M5 cell line and indicates an incomplete saturation of endogenous processed and  
 1086 HLA-presented MPO<sub>466</sub>-peptides. In the case of MPO<sub>145</sub>, this is true for all tested AML-  
 1087 cell lines.

1088

1089 **Figure 22: Cytokine release of TCR-transduced T cells after additional MPO-peptide pulsing.**  
 1090 **TCRF5.4- or TCR2.5D6-transduced T cells were analyzed for secretion of the cytokines GM-CSF,**  
 1091 **IFN- $\gamma$  and IL-2 after co-incubation with the AML-cell lines HL60-B7 (A), ML2-B7 (B), NB4-B7 (C)**  
 1092 **and SiG-M5 (D) with or without additional MPO-peptide pulsing. The secreted cytokines were meas-**  
 1093 **ured by multiplexed flow cytometry analyses. The results are shown in triplicates for n=2; adapted**  
 1094 **from [102].**

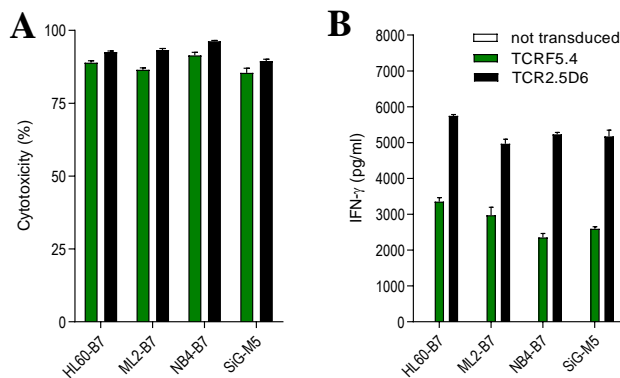

1095 3.3.5 Comparison of IFN- $\gamma$  release and cytotoxicity in effector to target ratio titrations

1096 In consecutive co-stimulation experiments, the cytotoxic potential was analyzed besides

1097 the IFN- $\gamma$  release for both TCR-transduced T cells. Notably, no substantial differences in

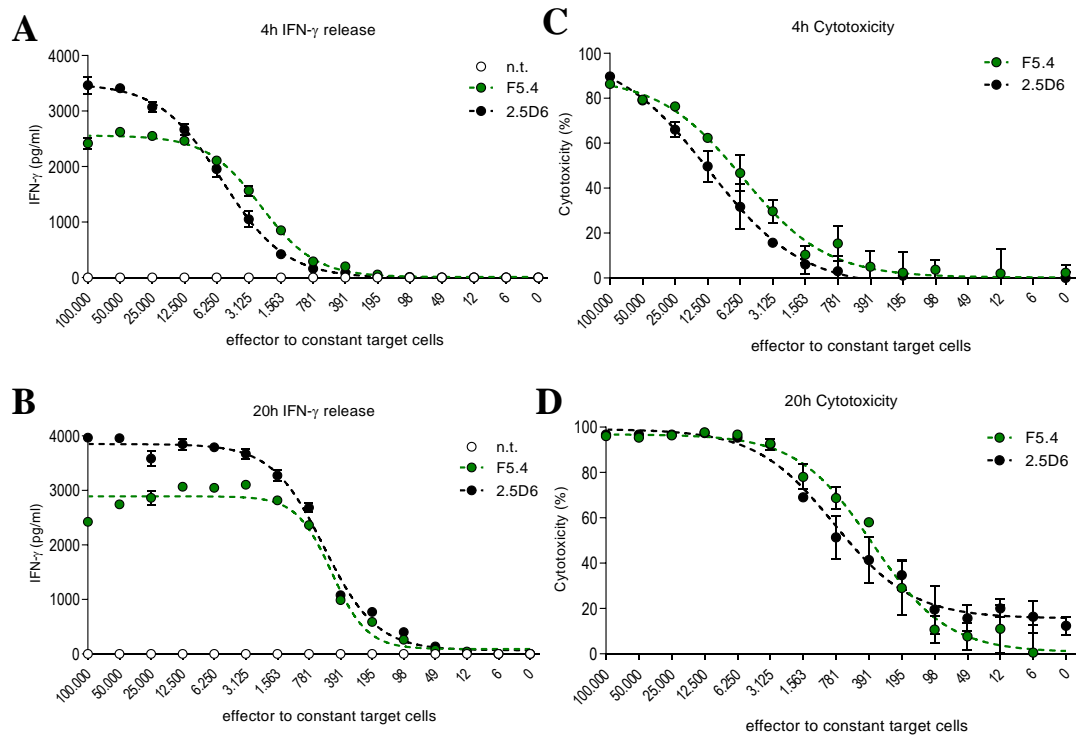

1098 cytotoxicity against the set of AML-target cell lines could be observed between both  
 1099 TCR-transduced T-cell populations (Figure 23A) although the IFN- $\gamma$  releases were again  
 1100 markedly different (Figure 23B).

1101 Effector to target titrations performed for 4h and 20h co-stimulation confirmed the previ-  
 1102 ous results. Again, the IFN- $\gamma$  release of TCRF5.4-transduced T cells was inferior for high  
 1103 E/T ratios compared to TCR2.5D6-transduced T cells (Figure 24A, B). However, the cy-  
 1104 totoxicity was similar for both TCRs with a trend for TCRF5.4 to be more cytotoxic than  
 1105 TCR2.5D6 over a broad range of E/T ratios (Figure 24 C, D). These finding could be  
 1106 confirmed by calculating the half-maximal ( $EC_{50}$ ) killing efficacy and IFN- $\gamma$  release for  
 1107 both TCR-transduced T cells at both time points (4h and 20h, Table 31). The  $EC_{50}$  values  
 1108 favor the TCRF5.4-transduced T cells regarding killing efficacy and responsiveness. Fur-  
 1109 thermore, there is a tendency that approximately  $\frac{1}{2}$  of TCRF5.4-transduced T cells are  
 1110 necessary to lyse target cells and to release IFN- $\gamma$  compared to TCR2.5D6.

1111

1112 **Figure 23: Cytotoxicity and IFN- $\gamma$  release of TCRF5.4- and TCR2.5D6-transduced T cells.**  
 1113 **Cytotoxicity (A) and IFN- $\gamma$  release (B) of selected AML-cell lines were analyzed after 20 h of co-**  
 1114 **incubation with either TCRF5.4- or TCR2.5D6-transduced T cells. The cytotoxicity was analyzed by**  
 1115 **flow cytometry and the IFN- $\gamma$  release was assessed by IFN- $\gamma$  ELISA.**

1116

1117 **Figure 24: Cytotoxicity and IFN- $\gamma$  release of TCRF5.4- and TCR2.5D6-transduced T cells at different**  
 1118 **effector to target ratios. Effector to target titrations ranging from 5:1 to 0.0031:1 were performed for**  
 1119 **selected quantities of TCR-transduced CD8<sup>+</sup> TCM co-incubated for either 4h (upper row) or 20h**  
 1120 **(lower row) with 20.000 NB4-B7 target cells. IFN- $\gamma$  release was measured by IFN- $\gamma$  ELISA (A, B).**  
 1121 **The cytotoxicity was analyzed by flow cytometry (C, D). Adapted from [102].**

1122 **Table 31: EC<sub>50</sub>-values of cytotoxicity and IFN- $\gamma$  release for effector to target titrations**

EC <sub>50</sub>	TCRF5.4 [cells]	TCR2.5D6 [cells]
<b>Cytotoxicity 4h</b>	4542 to 8459, E/T* 0.33	9188 to 19066, E/T 0.71
<b>Cytotoxicity 20h</b>	299 to 441, E/T 0.02	654 to 1007, E/T 0.04
<b>IFN-<math>\gamma</math> 4h</b>	2263 to 2541, E/T 0.12	5207 to 5887, E/T 0.28
<b>IFN-<math>\gamma</math> 20h</b>	417 to 532, E/T 0.02	510 to 615, E/T 0.03

1123 \*E/T = mean of T-cell range necessary to reach EC<sub>50</sub> at constant number of 20.000 engaged target cells.

1124 **3.4 In-vivo characterization of TCRF5.4 compared to TCR2.5D6**

1125 The in-vivo characterization of promising TCR-candidates using tumor mouse models is  
 1126 essential for preclinical testing. In the following in-vivo experiments, the NOD.Cg-Prk-  
 1127 dcscidII2rgtm1Wjl/SzJ (NSG) immunocompromised tumor mouse model was used

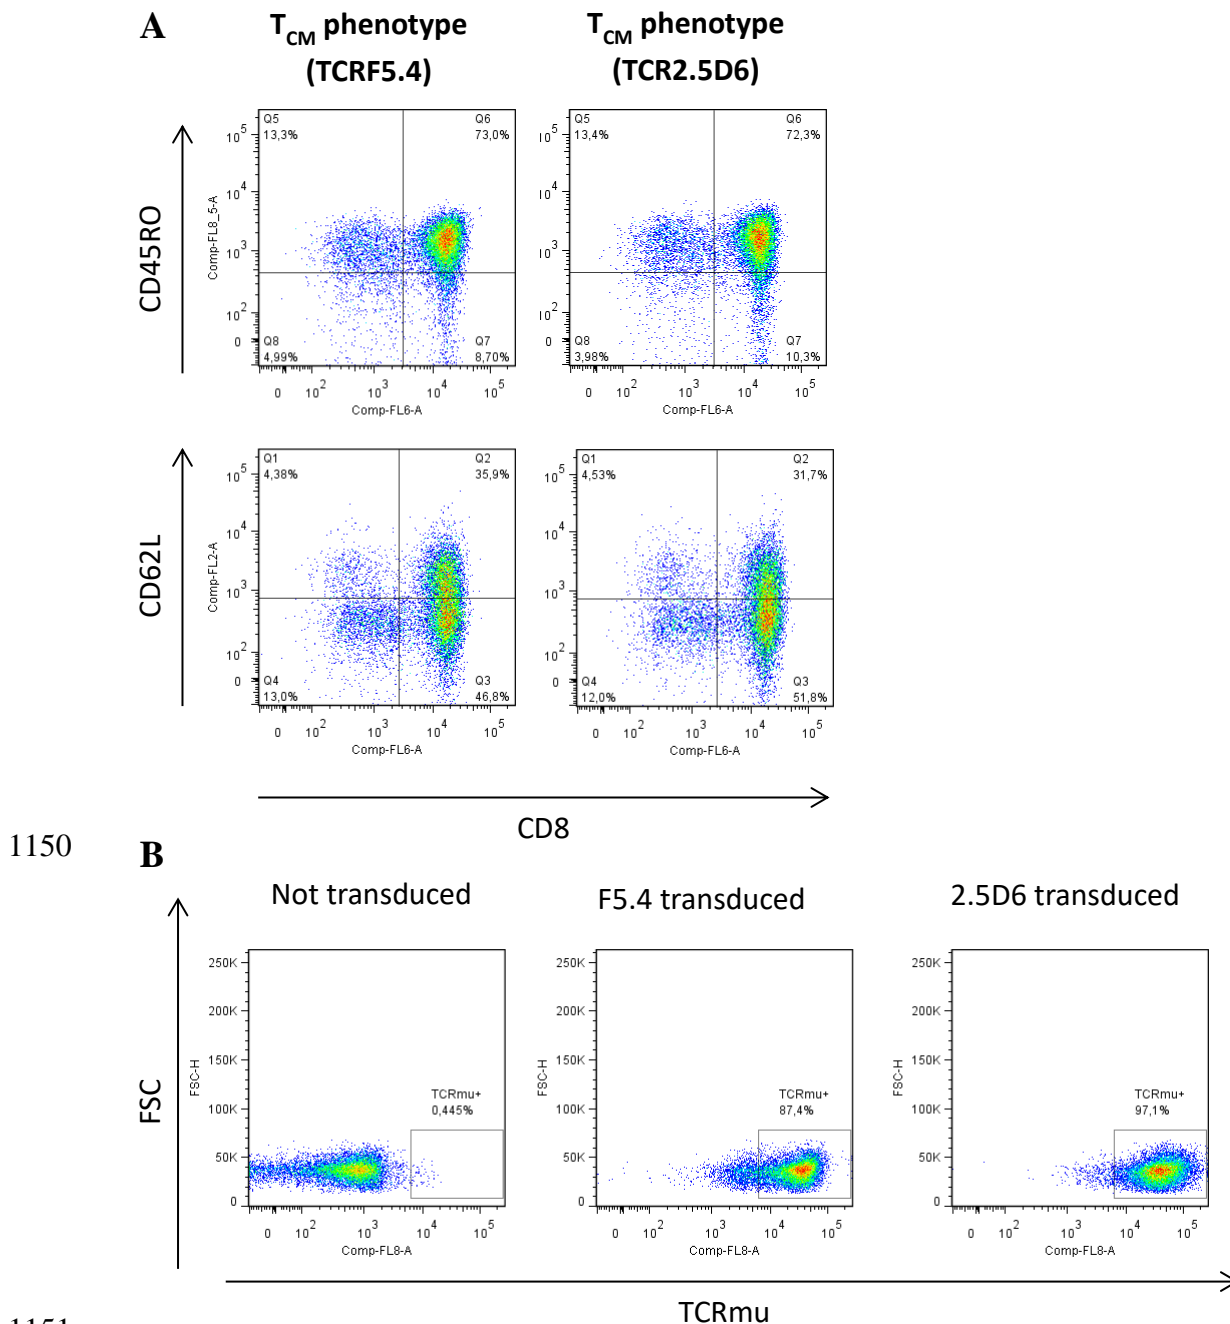

1128 [105]. In a first experiment, the HLA-B7-transgenic tumor cell line ML2 with endogenous  
1129 MPO expression was used for subcutaneous solid tumor inoculation. As this cell line  
1130 turned out to be positive for the HLA-B\*51:01 allele and the TCRF5.4 showed HLA-  
1131 B51-related cross-reactivity, the AML-cell lines HL60 and NB4 were initially tested in  
1132 ex vivo co-stimulation experiments for immunogenicity as an alternative tumor model.  
1133 Finally, the NB4 cell line was chosen for short- and long-term in-vivo experiments to  
1134 compare the tumor growth kinetics and overall survival of the mice after adoptive transfer  
1135 of TCRF5.4- and TCR2.5D6-transduced CD8<sup>+</sup> T cells enriched for the central memory  
1136 phenotype (CD8<sup>+</sup> T<sub>CM</sub>). All in-vivo experiments described below followed a defined  
1137 workflow. Starting with the T<sub>CM</sub>-phenotyping of the T-cell product and analysis of the  
1138 transduction efficacy at the day of (or one day before) adoptive T-cell transfer, the T-cell  
1139 products were tested in-vitro for their cytotoxicity and the capacity to release IFN- $\gamma$  upon  
1140 stimulation with cultured tumor cells used for tumor induction in the mice.

#### 1141 3.4.1 ML2-tumor mouse model

1142 The phenotyping and evaluation of TCR-transduction efficiency of TCRF5.4- or  
1143 TCR2.5D6-transgenic CD8<sup>+</sup> T<sub>CM</sub> phenotype was done two weeks after in-vitro expansion.  
1144 A representative phenotyping is shown in Figure 25A and B. Both T-cell products  
1145 were highly similar regarding CD45RO (~73% of living CD8<sup>+</sup> cells) and CD62L (~34%  
1146 of living CD8<sup>+</sup> cells) proportions. The transduction efficiency was ~87% for TCRF5.4  
1147 and ~97% for TCR2.5D6 and reflects the often-observed difference of approximately  
1148 10% in transduction efficiency between both TCRs.

1149

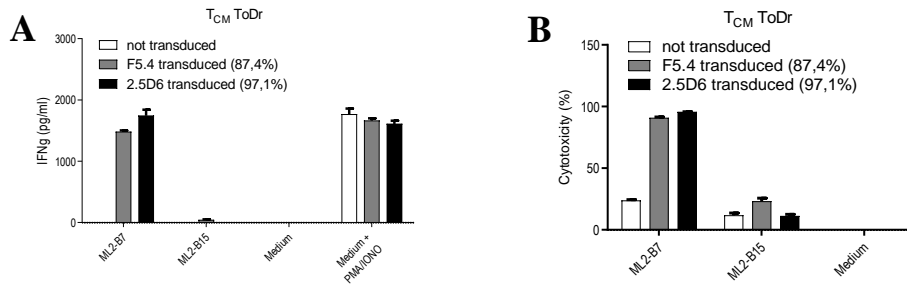

1150

1151

1152 **Figure 25: CD62L, CD45RO and TCR-transduction efficiency phenotyping of T-cell products used**  
 1153 **for the ML2-mice experiment. (A) Characterization of CD8<sup>+</sup> T-cells enriched for the T<sub>CM</sub> phenotype**  
 1154 **isolated from EDTA blood of healthy donors. PBMCs were depleted for the markers CD45RA<sup>+</sup>/CD4<sup>+</sup>**  
 1155 **and finally positively selected for CD62L<sup>+</sup> using magnetic beads. (B) Analysis of transgenic expres-**  
 1156 **sion of the constant murine TCR-β chain (TCRm) of either TCRF5.4- or TCR2.5D6-transduced**  
 1157 **CD8<sup>+</sup> T-cells enriched for the T<sub>CM</sub> phenotype by flow cytometry.**

1158 The in-vitro co-stimulation with HLA-B7-transgenic ML2 cells revealed a slightly en-  
 1159 hanced IFN-γ release for TCR2.5D6-transduced T cells compared to TCRF5.4-trans-  
 1160 duced T cells (Figure 26A) but similar levels of cytotoxicity for both TCRs assessed after

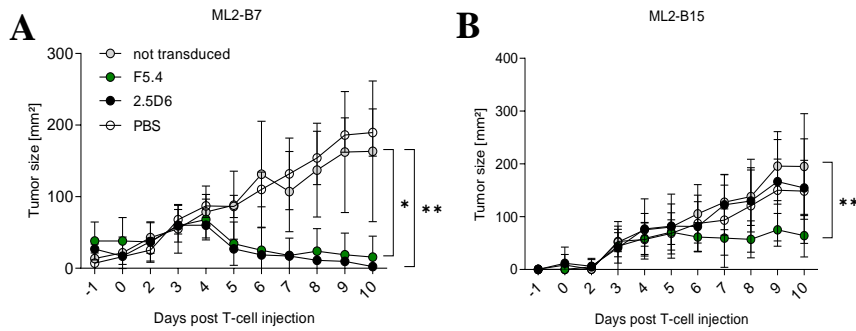

1161 24h of co-stimulation (Figure 26B). Compared to not transduced or TCR2.5D6-trans-  
 1162 duced T cells, the ML2-B15 cell line with endogenous HLA-B51 expression was partly  
 1163 lysed by TCRF5.4-transduced T cells.

1164

1165 **Figure 26: In-vitro reactivity of TCR-transduced T-cell products used for the ML2-NSG mouse**  
 1166 **model. (A) IFN- $\gamma$  release of either TCRF5.4- or TCR2.5D6-transduced T cells enriched for the central**  
 1167 **memory phenotype (T<sub>CM</sub>) measured by IFN- $\gamma$  ELISA and (B) cytotoxicity, evaluated by flow cytometry of remaining target cells after 20h of co-incubation with the ML2-B7 target cell line. The ML2-**  
 1168 **B15, not transduced T<sub>CM</sub> and PMA/Ionomycin-stimulated T<sub>CM</sub> served as controls. The mean and**  
 1169 **standard deviation is shown for triplicates.**  
 1170

1171 The tumor growth kinetics of ML2-B7-derived tumors was nearly identical for both TCR-  
 1172 transduced populations and compared to PBS and not transduced controls. Three days  
 1173 after T-cell injection the ML2-B7-derived tumors were controlled by the injected TCR-  
 1174 transgenic T-cells and tumor shrinkage finally started one day later. Up to day 10 after T-  
 1175 cell injection, the time point where the experiment was stopped, the mean tumor size of  
 1176 all tumors were continuously reduced below palpability (Figure 27A) while the PBS and  
 1177 the not transduced controls showed tumor growth continuously over the entire period.  
 1178 However, the growth kinetics of ML2-B15-derived tumors revealed a cross-reactivity of  
 1179 TCRF5.4-transduced T cells against the control tumors starting at day 3 after T-cell in-  
 1180 jection (Figure 27B) reflecting the in-vitro observed cytotoxicity results.

1181

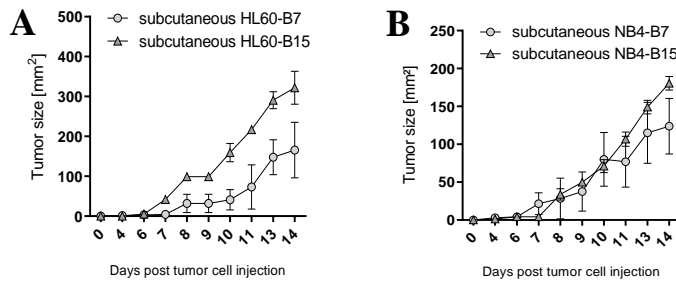

1182 **Figure 27: Subcutaneous growth of ML2-derived tumors after adoptive transfer of TCR-transduced**  
 1183 **T cells. (A) Growth of ML2-B7 and (B) ML2-B15 derived tumors at indicated days is shown for**  
 1184 **TCRF5.4- and TCR2.5D6-treated mice compared to not transduced, and PBS controls. Mean  $\pm$  s.d.**  
 1185 **of tumor size is indicated in mm<sup>2</sup>. ML2-B7 mice: not transduced n=6, PBS n=6, TCRF5.4 n=4 and**  
 1186 **TCR2.5D6 n=4 animals. ML2-B15 mice: not transduced and PBS n=6, TCRF5.4, and TCR2.5D6 n=7**  
 1187 **animals. The Mann-Whitney test was used for statistical analysis: \*p<0.05, \*\*p<0.01.**

1188 Taken together, the ML2 in-vivo experiment revealed highly similar tumor reduction po-  
 1189 tential of both TCR-transduced T-cell populations. However, results are not conclusive  
 1190 because of the interfering HLA-B51-related cross-reactivity against the ML2 cell line of  
 1191 the TCRF5.4.

### 1192 3.4.2 Ex vivo immunogenicity of NB4- and HL60-derived subcutaneous tumors

1193 Because of the HLA-B51-related cross-reactivity of the TCRF5.4 against the ML2 cell  
 1194 line, it was necessary to establish a new tumor model in the NSG mouse model. Therefore,  
 1195 the focus was laid on the two AML cell lines HL60 and NB4 with endogenous MPO  
 1196 expression. As a first step both cell lines were transduced either with HLA-B7 or HLA-  
 1197 B15 and subcutaneously injected into NSG mice after clonal expansion. The tumor  
 1198 growth was assessed for two weeks and the tumors finally removed to test the immuno-  
 1199 genicity ex vivo. Both AML-cell lines turned out to be suitable for subcutaneous tumor  
 1200 induction in NSG mice (Figure 28 A, B). The HL60 tumor cell line was more aggressive  
 1201 in tumor growth than the NB4 tumor cell line. The mean of tumor size at day 14 for HL60-  
 1202 B7-derived tumors (320 mm<sup>2</sup>) was nearly twice as high as for NB4-B7-derived tumors

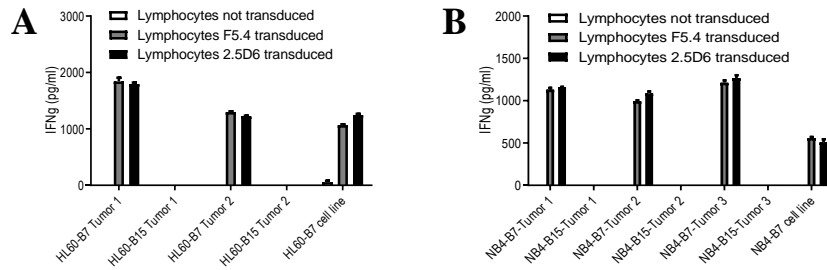

1203 (180 mm<sup>2</sup>). The overall tumor growth of their HLA-B15 counterparts (HL60-B15 and  
 1204 NB4-B15) was even faster compared to the HLA-B7-derived tumors, however, still re-  
 1205 flects the superior growth of HL60-derived tumors compared to NB4-derived tumors.

1206

1207 **Figure 28: Tumor growth of subcutaneous injected HL60 and NB4 tumor cell lines in NSG mice.**  
 1208 **Subcutaneous growth of (A) HL60-B7 and HL60-B15 or (B) NB4-B7 and NB4-B15 derived tumors**  
 1209 **at indicated days. In each mouse, two tumors were induced by subcutaneous injections (left flank**  
 1210 **HLA-B7<sup>+</sup> tumor cells; right flank the HLA-B15<sup>+</sup> tumor cells). The mean and standard deviation is**  
 1211 **shown for triplicates.**

1212 After resection of the tumors and single cell preparations, the tumor cells were used in  
 1213 co-stimulation experiments with either not transduced, TCRF5.4- or TCR2.5D6-trans-  
 1214 duced lymphocytes. Both tumor-derived cell lines elicited robust IFN- $\gamma$  release of TCR-  
 1215 transduced lymphocytes after co-incubation and were even more immunogenic than cell  
 1216 lines cultured in-vitro. The overall IFN- $\gamma$  release in HL60 co-stimulation experiments  
 1217 (Figure 29A) was even higher compared to the NB4 co-stimulation (Figure 29B) for two  
 1218 independent TCR-transduced donor T-lymphocytes. The expression of HLA-B7eGFP- or  
 1219 HLA-B15eGFP in both tumor-derived cell lines could be verified by flow cytometry.

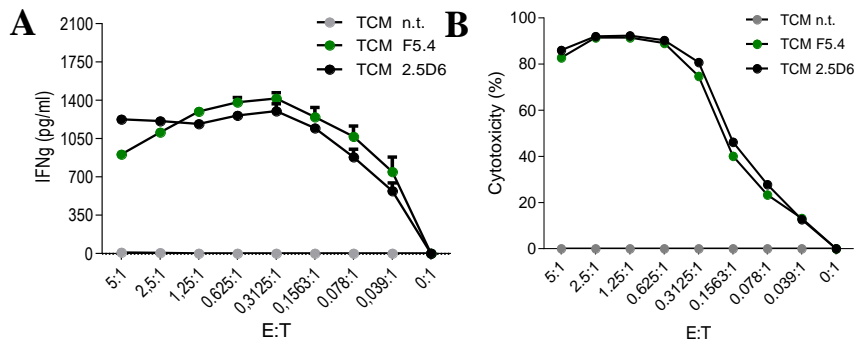

1220 **Figure 29: T-cell reactivity of TCRF5.4- and TCR2.5D6-transduced Lymphocytes against ex vivo pro-**  
 1221 **cessed HL60- and NB4-derived tumors grown in NSG mice. IFN- $\gamma$  release of either TCRF5.4- or**  
 1222 **TCR2.5D6-transduced T-lymphocytes measured by IFN- $\gamma$  ELISA after 20h of co-incubation with**  
 1223 **single cell suspensions of (A) HL60-B7 or (B) NB4-B7 derived subcutaneous tumors grown in NSG**  
 1224 **mice. The HLA-B15<sup>+</sup> tumors, T cells without TCR-transduction and in-vitro cultured target cell lines**  
 1225 **were used as controls. The mean and standard deviation is shown for triplicates.**

### 1226 3.4.3 NB4-tumor mouse model

1227 For the following in-vivo experiments, the NB4 tumor cell line was chosen because of its  
 1228 moderate tumor growth kinetics and the reliable in-vitro results (see chapter 3.4.2). In  
 1229 initial mouse trials, the tumor growth of mice that received either a not transduced, a  
 1230 TCRF5.4-transduced or a TCR2.5D6-transduced T-cell product was analyzed. The ex-  
 1231 periment was stopped after seven days after adoptive T-cell transfer to assess tumor  
 1232 weight and TCR-transduced T-cell infiltration into the tumor, lung, spleen, blood and  
 1233 bone marrow. The initial phenotyping of the CD8<sup>+</sup>T<sub>CM</sub> one day prior to T-cell injection  
 1234 resulted in ~83% CD8<sup>+</sup>CD45RO<sup>+</sup> and ~23% CD8<sup>+</sup>CD62L<sup>+</sup> T cells within the TCRF5.4  
 1235 T-cell product and ~74% CD8<sup>+</sup>CD45RO<sup>+</sup> and ~10% CD8<sup>+</sup>CD62L<sup>+</sup> T cells within the  
 1236 TCR2.5D6 T-cell product. The transduction efficiency was ~85% for TCRF5.4-trans-  
 1237 duced T cells and ~88% for the TCR2.5D6-transduced T cells. The mean fluorescent  
 1238 intensity of the transgenic TCR2.5D6 was higher (23840) compared to TCRF5.4 (14605).  
 1239 To test the in-vitro reactivity of the T-cell product before T-cell injection, IFN- $\gamma$  release  
 1240 (Figure 30A) and cytotoxicity (Figure 30B) were assessed in effector to target titration  
 1241 assays. Except for the reduced IFN- $\gamma$  release of TCRF5.4-transduced T cells at the highest

1242 effector to target ratio of 5:1, the TCRF5.4 T-cell product showed very similar responses  
 1243 in cytotoxicity and IFN- $\gamma$  release compared to the TCR2.5D6 T-cell product in-vitro.

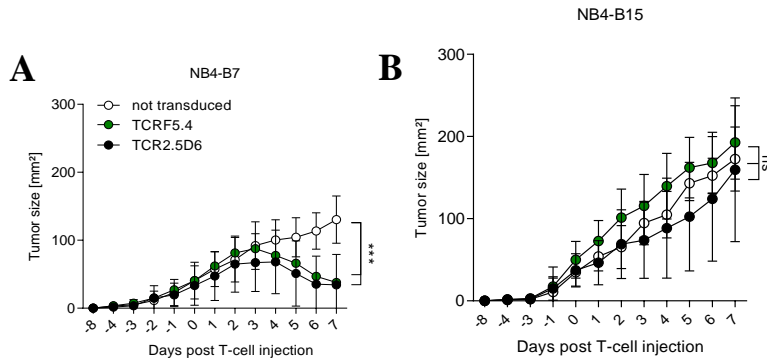

1244

1245 **Figure 30: Effector to target titration of TCRF5.4- and TCR2.5D6-transduced CD8<sup>+</sup> T<sub>CM</sub> against the**  
 1246 **target cell line NB4-B7. (A) IFN- $\gamma$  release of either TCRF5.4- or TCR2.5D6-transduced T cells en-**  
 1247 **riched for the central memory phenotype (T<sub>CM</sub>) measured by IFN- $\gamma$  ELISA and (B) cytotoxicity eval-**  
 1248 **uated by flow cytometry of remaining target cells after 20h of co-incubation with the NB4-B7 target**  
 1249 **cell line at indicated effector to target ratios. As a negative control, not transduced T cells were used.**  
 1250 **The mean and standard deviation is shown for each data point in triplicates.**

1251 Interestingly, tumor growth in both mice populations receiving either TCRF5.4- or  
 1252 TCR2.5D6-transduced T-cells was again similar (Figure 31) as seen before in the ML2  
 1253 mouse model (see chapter 3.4.1). Although the reduction in tumor size was not as effec-  
 1254 tive as for the ML2 tumors, both TCR-transduced T-cells showed a tumor control starting  
 1255 at day 2 to 3 with a continuous tumor reduction starting at day 3 to 4 (Figure 31A). The  
 1256 NB4-B15 control tumors displayed an unaffected tumor growth for all three mice popu-  
 1257 lations that received either not transduced, TCRF5.4-transduced or TCR2.5D6-trans-  
 1258 duced T cells (Figure 31B).

1259

1260

1261 **Figure 31: Subcutaneous growth of NB4-derived tumors after adoptive transfer of TCR-transduced**  
 1262 **T cells. (A) Growth of NB4-B7 and (B) NB4-B15 derived tumors at indicated days is shown for**  
 1263 **TCRF5.4- and TCR2.5D6-treated mice compared to not transduced controls. Mean  $\pm$  s.d. of tumor**  
 1264 **size is indicated in mm<sup>2</sup>. NB4-B7 mice: not transduced n=12, TCRF5.4 n=14, and TCR2.5D6 n=12**  
 1265 **animals. NB4-B15 mice: not transduced n=6, TCRF5.4 n=7, and TCR2.5D6 n=7 animals. The Mann-**  
 1266 **Whitney test was used for statistical analysis: \*\*\*p<0.001. Adapted from [102].**

1267 To consider the tumor growth regardless of mouse-individual tumor sizes at each meas-  
 1268 ured time point, the first deviation of each growth kinetic was calculated using the non-  
 1269 linear fitting algorithms provided by GraphPad Prism 8. Afterward, the deviation curves  
 1270 were plotted using the smoothing parameters of the software as follows: Numbers of  
 1271 neighbors to average = 5; Orders of the smoothing polynomial = second order (Figure  
 1272 32). This consideration of tumor growth is not biased by individual tumor size in mice  
 1273 causing high standard deviations and distorted mean calculation in small populations. In-  
 1274 stead, only the slopes of tumor growth for each time point is considered and revealed for  
 1275 both TCR-transduced groups an increasing tumor growth rate till the time point of T-cell  
 1276 injection. Closely after T-cell injection, the tumor growth rates slowed down until day 4  
 1277 for both TCR-transduced groups and turned finally into continuous tumor shrinkage until  
 1278 the end of the experiment at day 7. Both TCR-transduced groups are significantly differ-  
 1279 ent from the not transduced T-cell group that served as a negative control and displayed  
 1280 positive tumor growth rates over the entire period.

1281

1282 **Figure 32: Analysis of tumor growth rates of NB4-derived tumors in NSG mice. The first deviation**  
 1283 **of tumor growth is shown for TCRF5.4- (green) and TCR2.5D6-treated mice (black) against the con-**  
 1284 **trol of mice treated with not transduced T cells (gray). The determination of tumor growth equations**  
 1285 **and their first deviation was calculated using GraphPad Prism 8's smoothing and differentiating**  
 1286 **analysis tools (smoothing: numbers of neighbors to average = 5 and order of the smoothing polyno-**  
 1287 **mial = 2). X-axis: Time in days starting 8 days before T-cell injection to 7 days after T-cell injection,**  
 1288 **dashed line = time point of T-cell injection; Y-axis: Growth rates/slopes of tumors (1<sup>st</sup> deviation of**  
 1289 **tumor growth). The unpaired t-test was used for statistical analysis: TCRF5.4: \*p = 0.237;**  
 1290 **TCR2.5D6: \*\*p = 0.0057.**

1291 The ex vivo analysis of tumor weight for all three mouse groups confirmed the results of  
 1292 tumor growth measurements and displayed a significantly reduced tumor weight in  
 1293 TCRF5.4- and TCR2.5D6 –treated mice compared to the not transduced control group.  
 1294 No significant difference between the tumor weights of the TCRF5.4- (median = 0.21)  
 1295 and TCR2.5D6 group (median = 0.15) could be observed (Figure 33). Summarized, the  
 1296 tumor growth rates and the tumor weights of the TCRF5.4- and TCR2.5D6 group are  
 1297 highly similar and indicate comparable tumor killing efficiency of both TCRs in-vivo.

1298

1299 **Figure 33: Tumor weight at day 7 of NSG-mice receiving TCR-transduced T-cell product. Not TCR-**  
 1300 **transduced T cells (n.t.) n = 9, TCRF5.4 n = 12, TCR2.5D6 n = 10. The Mann-Whitney test was used**  
 1301 **for statistical analysis: \*\*\*p<0.001. Adapted from [102].**

1302 Looking at the T-cell distribution within the tumors, the levels of CD45<sup>+</sup>CD3<sup>+</sup> T cells for  
 1303 both TCR-transduced groups were significantly elevated compared to the not transduced  
 1304 control. Both TCR-transduced groups share a median of T-cell infiltration of around 1%  
 1305 compared to the median of 0.3% for the not transduced group. All NB4-B15 control tu-  
 1306 mors displayed no T-cell infiltration (Figure 34).

1307

1308 **Figure 34: T-cell infiltration in NB4-derived tumors in NSG mice. Percentage of viable CD45<sup>+</sup>CD3<sup>+</sup>**  
 1309 **T cells in NB4-B7 or NB4-B15 extracted tumor material of mice treated with not TCR-transduced T**  
 1310 **cells (n.t.), TCRF5.4- or TCR2.5D6-transduced T cells analyzed by flow cytometry. The Mann-Whit-**  
 1311 **ney test was used for statistical analysis: \*p<0.05. Adapted from [102].**

1312 The results of the T-cell infiltration into the bone marrow, blood, lung, and spleen re-  
 1313 vealed only significant differences within the lung in TCRF5.4-treated mice. Here, higher  
 1314 levels of CD3<sup>+</sup>TCRmu<sup>+</sup> TCRF5.4-transduced T cells (median = 24.7) were found com-  
 1315 pared to TCR2.5D6-transduced T cells (median = 6.9) in the lungs of TCR2.5D6-treated  
 1316 mice (Figure 35).

1317

1318 **Figure 35: T-cell infiltration in bone marrow, blood, lung, and spleen of NSG mice after T-cell injection.**  
 1319 **Percentage of viable CD3<sup>+</sup>TCR $\mu$ <sup>+</sup> T cells in indicates samples of mice treated with not TCR-**  
 1320 **transduced T cells (n.t.), TCRF5.4- or TCR2.5D6-transduced T cells analyzed by flow cytometry. The**  
 1321 **Mann-Whitney test was used for statistical analysis: \*\*p<0.01. Adapted from [102].**

1322 3.4.4 Long-term survival of NB4 tumor mice after adoptive T-cell transfer

1323 Within the short period of 15 days of the previous in-vivo experiments, no clear differ-  
 1324 ences in tumor growth between TCRF5.4- or TCR2.5D6-treated mice could be observed.

1325 Therefore, the next mouse trials focused on the overall survival of the mice.

1326 Phenotyping of the CD8<sup>+</sup>T<sub>CM</sub> at the day of T-cell injection showed for TCRF5.4-trans-  
 1327 duced T cells ~62% of CD8<sup>+</sup>CD45RO<sup>+</sup> cells, ~26% of CD8<sup>+</sup>CD62L<sup>+</sup> cells and a TCR-  
 1328 transduction efficiency of ~85%. For the TCR2.5D6-transduced T cells ~61%, ~27%, and  
 1329 87%, respectively. Within this experiment, the transduction efficiencies as well as the  
 1330 TCR-surface densities were highly comparable (MFI ~ 13,000). The responsiveness of  
 1331 both TCR-transgenic T-cell products was tested by in-vitro co-stimulation experiments  
 1332 and IFN- $\gamma$  release as well as cytotoxicity were assessed. Again, the IFN- $\gamma$  release of  
 1333 TCRF5.4-transduced T cells (2600 pg/ml) was inferior compared to the TCR2.5D6-trans-  
 1334 duced T cells (3400 pg/ml) (Figure 36A). However, both TCR-transgenic T cells showed  
 1335 again highly similar cytotoxicity levels (~97%) against the in-vitro cultured NB4-B7 cell  
 1336 line used for tumor induction in recipient mice (Figure 36B).

1337

1338 **Figure 36: T-cell reactivity of TCRF5.4- and TCR2.5D6-transduced CD8<sup>+</sup>T<sub>CM</sub> against the NB4-B7**  
 1339 **tumor cell line used for the long-term mouse experiment. (A) IFN-γ release of either TCRF5.4- or**  
 1340 **TCR2.5D6-transduced T cells enriched for the central memory phenotype (T<sub>CM</sub>) measured by IFN-**  
 1341 **γ ELISA and (B) cytotoxicity evaluated by flow cytometry of remaining target cells after 20h of co-**  
 1342 **incubation with the NB4-B7 target cell line. Not transduced T cells were used as a negative control.**  
 1343 **The mean and standard deviation is shown for each data point in triplicates for (A). In (B) the trip-**  
 1344 **licates were pooled before the analysis by flow cytometry in order to have enough detectable events**  
 1345 **for the measurement. Adapted from [102].**

1346 The tumor growth for individual mice of the not transduced group, TCRF5.4- and  
 1347 TCR2.5D6-transduced group is shown in Figure 37. In this long-term experiment, sub-  
 1348 stantial differences between TCRF5.4 and TCR2.5D6 became apparent. Similar to previ-  
 1349 ous experiments (see chapter 3.4.3), both groups treated with the TCR-transduced T cells  
 1350 showed at the beginning comparable tumor control and reduction of the tumor's sizes.  
 1351 However, starting at day 6 the tumors in TCRF5.4-treated mice started to progress again.  
 1352 In contrast, in nearly all TCR2.5D6-treated mice the tumor sizes were reduced below  
 1353 palpability at day 12. Interestingly, approximately one week later (day19), 4 out of 6  
 1354 TCR2.5D6-treated mice relapsed. The remaining mice relapsed at day 32 and day 36 after  
 1355 T-cell injection, respectively. The control group treated with not transduced T cells  
 1356 showed tumor growth continuously over the entire period.

1357 The median survival of mice treated with not transduced T cells was 22 day, for TCR-  
 1358 F5.4-treated mice 28 days and for TCR2.5D6-treated mice 46 days. Each group is signif-  
 1359 icantly different from the others with the TCR2.5D6 group showing superior overall sur-  
 1360 vival (Figure 38).

1361

1362 **Figure 37: Subcutaneous growth of NB4-derived tumors after adoptive transfer of TCR-transduced**  
 1363 **CD8<sup>+</sup>T<sub>CM</sub> in long-term NSG-mice experiment. Growth of NB4-B7 derived tumors at indicated days**  
 1364 **is shown for TCRF5.4- and TCR2.5D6-treated mice compared to not transduced controls. Tumor size**  
 1365 **is indicated in mm<sup>2</sup>. Not transduced, TCRF5.4 and TCR2.5D6 n = 7 animals. Adapted from [102].**

1366

1367 **Figure 38: Survival curve of TCRF5.4- or TCR2.5D6-treated NSG mice. Median survival: Not trans-**  
 1368 **duced T cell-treated mice = 22 days, TCR.F5.4-treated mice = 28 days, TCR2.5D6-treated mice = 46**  
 1369 **days. Statistical analysis was done using the Log-rank (Mantel-Cox) test \*\*\*p<0.001 [102].**

1370 For a better overview and to compare the results to the previous experiment (see chapter  
 1371 3.4.3), Figure 39 displays the same data set as shown in Figure 37 only with the mean of  
 1372 each group together with the standard deviation. For the reason of data integrity, the  
 1373 growth curves are only displayed until the last time point with all mice being still alive in  
 1374 each group. This procedure shortened the displayed period for the TCRF5.4 cohort from  
 1375 20 days to 15 days and for the TCR2.5D6 cohort from 58 days to 34 days. Compared to  
 1376 the growth curves shown in the short-term in-vivo experiment for the NB4-mouse model,  
 1377 there is an astonishing similarity of both TCR-transduced groups until day 6 to 7. Day 7,  
 1378 in turn, is the point of inflection between TCRF5.4- and TCR2.5D6-treated mice. While  
 1379 the TCR2.56 cohort showed ongoing tumor reduction down to the limit of detection, all  
 1380 tumors in the TCRF5.4 cohort indicate either an early tumor escape mechanism or a loss

1381 of T-cell functionality after an initial period of immunogenicity. The tumors in the  
 1382 TCR2.5D6 cohort relapsed later around day 20.

1383

1384 **Figure 39: Long-term growth of subcutaneous NB4 tumors after adoptive transfer of TCR-trans-**  
 1385 **duced CD8<sup>+</sup>T<sub>CM</sub>. Growth of NB4-B7 derived tumors at indicated days is shown for TCRF5.4- and**  
 1386 **TCR2.5D6-treated mice compared to not transduced controls. Mean  $\pm$  s.d. of tumor size in mm<sup>2</sup>. Not**  
 1387 **transduced, TCRF5.4 and TCR2.5D6: each n = 7 animals.**

1388 Considering the first derivatives of the mean tumor growth (Figure 40), the initial course  
 1389 of growth rates for both TCR-treated cohorts was again very similar. However, around  
 1390 day 6 to 7 it became apparent that the TCRF5.4-treated mice did not enter a sustained  
 1391 tumor reduction phase (green line stays above the dashed horizontal line). Afterward, the  
 1392 tumor growth rates increased again. In contrast, the TCR2.5D6-treated mice entered a  
 1393 prolonged tumor reduction phase of 11 days starting at day 7 (black curve below the  
 1394 dashed horizontal line) before the tumors displayed again increased growth rates and tu-  
 1395 mor progression. Taken together, day 6 to 7 after T-cell injection is a turning point in the  
 1396 NB4-tumor model that revealed visible differences in tumor killing efficacy between the  
 1397 TCRF5.4- and TCR2.5D6-T-cells populations.

1398

1399 **Figure 40: Analysis of tumor growth rates of NB4-derived tumors in NSG mice: The first deviation**  
 1400 **of tumor growth is shown for TCRF5.4- (green) and TCR2.5D6-treated mice (black) against the**  
 1401 **control of mice treated with not transduced T cells (gray). The determination of tumor growth**  
 1402 **equations and their first deviation was calculated using GraphPad Prism 8's smoothing and**  
 1403 **differentiating analysis tools (smoothing: numbers of neighbors to average = 5 and order of the**  
 1404 **smoothing polynomial = 2). X-axis: Starting 7 days before T-cell injection (-7) to 34 days after**  
 1405 **T-cell injection, vertical dashed line = time point of T-cell injection; Y-axis: Growth rates/slopes of**  
 1406 **tumors (1<sup>st</sup> deviation of tumor growth).**

1407 At day 13, the last time point where in the three cohorts all mice were still alive, the tumor  
 1408 sizes were compared to each other (Figure 41). The tumors were significant different with  
 1409 median sizes of 320 mm<sup>2</sup> for the not transduced cohort, 210 mm<sup>2</sup> for the TCRF5.4-treated  
 1410 cohort and 2 mm<sup>2</sup> for the TCR2.5D6-treated cohort. Summarized, the TCR2.5D6-treated  
 1411 mice showed a superior tumor response after T-cell injection.

1412

1413 **Figure 41: Tumor sizes of NB4-derived tumors at day 13 after T-cell injection. Not TCR-transduced**  
 1414 **T cells (n.t.), TCRF5.4 and TCR2.5D6: n = 7. The Mann-Whitney test was used for statistical**  
 1415 **analysis: \*\*\*p<0.001.**

1416 To assess if a loss of HLA-B7 expression was responsible for the tumor escapes within  
 1417 the different TCR-groups, single cell suspensions of ex vivo tumors were analyzed by  
 1418 flow cytometry for HLA-B7- and GFP-expression (Figure 42). The results show, that the

1419 tumors of the TCRF5.4 group still expressed the HLA-B7 restriction element on the sur-  
1420 face of the cells, while tumors of the TCR2.5D6 group had a loss of HLA-B7 expression.

1421

1422 **Figure 42: Loss of transgenic HLA-B7 expression in TCR2.5D6-treated mice. Percentage of viable**  
1423 **GFP<sup>+</sup>CD45<sup>+</sup>HLA-B7<sup>+</sup> in extracted tumor material of mice treated with not transduced (n.t.),**  
1424 **TCRF5.4- or TCR2.5D6-transduced T cells analyzed by flow cytometry. n = 7 for all three groups of**  
1425 **mice. The Mann-Whitney test was used for statistical analysis: \*\*\*p<0.001. Adapted from [102].**

1426 Similar to the previous mouse experiment (see chapter 3.4.3), the lungs of mice treated  
1427 with TCRF5.4-transduced T cells showed higher infiltration of TCRm<sup>+</sup> T cells compared  
1428 to mice treated with TCR2.5D6-transduced T cells (Figure 43). This time, also the blood  
1429 and the spleen showed significant higher infiltration of TCRm<sup>+</sup> T cells in TCRF5.4-  
1430 treated mice compared to the TCR2.5D6-treated group. Of note, each mouse was ana-  
1431 lyzed at individual time of death or the need to sacrifice it. The data points for the  
1432 TCR2.5D6-treated mice were collected substantially later because of the prolonged sur-  
1433 vival of this group. The absence of TCR-2.5D6-transduced mice in these cases could not  
1434 directly be compared to the TCRF5.4-treated mice. The number of TCR2.5D6 T cells  
1435 may decreased after tumor eradication and absence of pro-survival stimuli since the re-  
1436 lapsed tumor cells were negative for the correct HLA-B7 restriction elements. Further-  
1437 more, the prolonged period of TCR2.5D6-transduced T cells in the mice without support-  
1438 ive T-cell milieu together with the challenging tumor conditions may have exhausted the  
1439 T cells.

1440

1441 **Figure 43: T-cell infiltration in bone marrow, blood, lung, and spleen of NSG mice after T-cell injection.**  
1442 **Percentage of viable CD3<sup>+</sup>TCR<sup>mu+</sup> T cells in indicates samples of mice treated with not TCR-**  
1443 **transduced T cells (n.t.), TCRF5.4- or TCR2.5D6-transduced T cells analyzed by flow cytometry. For**  
1444 **samples and groups n = 7. Adapted from [102].**

### 1445 3.5 Characterization of MPO<sub>145</sub> and MPO<sub>466</sub>

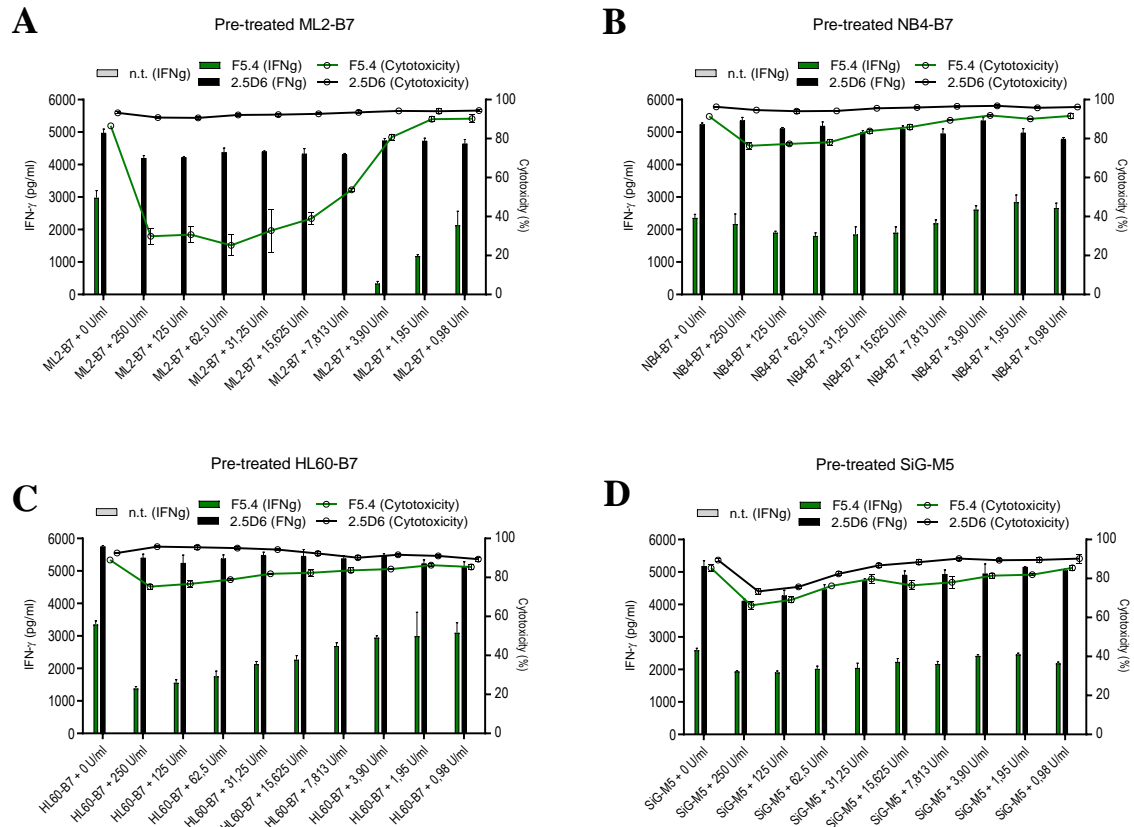

1446 The observed differences in survival and tumor growth in the long-term in-vivo experi-  
1447 ment (see chapter 3.4.4) despite the similarity between both TCR regarding  $k_{\text{off}}$ -rate, func-  
1448 tional avidity and cytotoxicity in-vitro, turned the focus to the characterization of the pep-  
1449 tide-MHC complexes. The goal was to characterize the impact of biochemical differences  
1450 of both peptide-MHC complexes on the observed in-vivo and in-vitro results. First, the  
1451 IFN- $\gamma$  release of TCR-transduced T cells after co-stimulation with IFN- $\gamma$  pretreated  
1452 AML-cell lines was analyzed in order to estimate the impact of IFN- $\gamma$  on HLA-expression  
1453 and proteasome composition in target cells. In parallel, the MPO-peptide surface presen-  
1454 tation on the same set of AML-cell lines was analyzed by mass spectrometry using an  
1455 immunopeptidomics approach. In a second step, prolonged peptide variants of MPO<sub>145</sub>  
1456 were examined to exclude that also a nonameric variants might be responsible for the  
1457 observed TCRF5.4 T-cell responses. Following this, UV-mediated peptide exchanges and  
1458 differential scanning fluorimetry assays were performed to compare the stability of the  
1459 MPO-MHC complexes. In a last step, detailed p-MHC modeling was done in cooperation  
1460 with the group of Iris Antes from the Center for Integrated Protein Science at the Tech-  
1461 nical University Munich in Freising to visualize critical binding characteristics of the  
1462 MPO-peptides to HLA-B7 and to describe the results observed in the amino acid substi-  
1463 tution assays.

#### 1464 3.5.1 IFN- $\gamma$ release and cytotoxicity of T cells after co-incubation with IFN- $\gamma$ 1465 pretreated target cells

1466 The four AML-cell lines NB4, HL60, ML2 with transgenic HLA-B7 expression and the  
1467 SiG-M5 cell line with endogenous HLA-B7 expression were pretreated for 24h with  
1468 graded amounts of IFN- $\gamma$  to analyze the effect of IFN- $\gamma$  on the target cell line and the  
1469 immune response of TCR-transduced T cells in consecutive co-culture experiments.

1470 TCRF5.4-transduced T cells showed an IFN- $\gamma$  dose-dependent response to all four IFN-  
1471  $\gamma$  pretreated AML-cell lines. The most potent effect could be observed for the ML2 cell  
1472 line with disrupted IFN- $\gamma$  release by TCRF5.4-transduced T cells starting from 250 U/ml  
1473 down to 7.8 U/ml IFN- $\gamma$  used for the pretreatment. The cytotoxicity of the TCRF5.4  
1474 T cells was affected accordingly and reduced to 20% for the highest IFN- $\gamma$  pretreatment  
1475 concentrations (Figure 44A). Both effects were also observed for the other AML-cell lines  
1476 NB4-B7, HL60-B7 and SiG-M5 but to a lower extent (Figure 44 B-D). Ranging the  
1477 AML-cell lines according to their immunogenicity after IFN- $\gamma$  pretreatment gives the fol-  
1478 lowing order: NB4< SiG-M5<HL60<ML-2. Interestingly, the effects of reduced IFN- $\gamma$   
1479 release and reduced cytotoxicity for TCR2.5D6-transduced T cells could only be ob-  
1480 served for the SiG-M5 cell line (Figure 44D). In all other cell lines, the effect was either  
1481 absent or marginally low.

1482 Taken together, both TCR-transgenic T cells showed different kinds of quantitative and  
1483 qualitative immune responses against IFN- $\gamma$  pretreated AML-cell lines. TCRF5.4-trans-  
1484 duced T cells showed partially high sensitivity and substantial diminished immune re-  
1485 sponses against a part of IFN- $\gamma$  pretreated target cells. The HLA-B7 transgenic AML-cell  
1486 lines revealed no significant changes in HLA-B7 expression while it was slightly elevated  
1487 on the SiG-M5 cell line with endogenous HLA-B7 expression after IFN- $\gamma$  pretreatment.

1488

1489 **Figure 44: T-cell responses against IFN- $\gamma$  pretreated AML-target cell lines. IFN- $\gamma$  release (bar plot)**  
 1490 **of either TCR5.4- or TCR2.5D6-transduced T cells measured by IFN- $\gamma$  ELISA and cytotoxicity**  
 1491 **(line) evaluated by flow cytometry of remaining target cells after 24h of co-incubation with four dif-**  
 1492 **ferent AML cell lines. The target cell lines ML2-B7 (A), NB4-B7 (B), HL60-B7 (C) and SiG-M5 (D)**  
 1493 **were treated with indicated amounts of IFN- $\gamma$  for 24h before the co-stimulation with TCR-transduced**  
 1494 **T cells. Not transduced T cells and non-treated AML target cells were used as a negative control and**  
 1495 **as a baseline for IFN- $\gamma$  release of T cells, respectively. The results are shown for one representative**  
 1496 **experiment (n = 2) and the mean  $\pm$  s.d. is shown for each data point in triplicates.**

1497 Because of nearly unchanged HLA-B7 expressions in the IFN- $\gamma$  pretreated AML-cell  
 1498 lines, reduced immune responses of TCR5.4-transduced T cells may not be explained  
 1499 sufficiently by this mechanism. To test whether a change in the immune proteasome com-  
 1500 position and a changed peptide processing could be the reason for the observed difference  
 1501 in immune response after IFN- $\gamma$  pretreatment, the mRNA levels of the three proteasome  
 1502 subunits PSMB 8, PSMB 9 and PSMB 10 were analyzed. Additionally, the MPO<sub>145</sub>- and  
 1503 MPO<sub>466</sub>-peptide presentation on the surface of the target cells was relatively quantified

1504 by mass spectrometry to estimate a change in peptide levels after IFN- $\gamma$  pretreatment (see  
1505 chapter 3.5.2).

1506 As described, the proteasomal subunits PSMB 8, PSMB 9 and PSMB 10 are assembled  
1507 to the immunoproteasome triggered by IFN- $\gamma$  [106]. This assembly can result in an en-  
1508 hanced and more diverse peptide processing and HLA-dependent peptide presentation on  
1509 the surface of cells [107]. The IFN- $\gamma$  pretreatment for 24h with 200 U/ml resulted in a  
1510 substantial increase of mRNA for all three PSMB subunits in the AML-cell line panel  
1511 compared to not treated controls (Figure 45). The Jurkat76 cell line served as a positive  
1512 control for the immunoproteasome after IFN- $\gamma$  induction. The ML2-B7 cell line showed  
1513 the highest increase in all three PSMB subunits after the IFN- $\gamma$  treatment followed by the  
1514 SiG-M5, NB4-B7, and HL60-B7 cell line. Notably, the proportional distribution of the  
1515 subunits differed between these cell lines. In all cell lines, especially in SiG-M5 and NB4,  
1516 PSMB 8 had the smallest proportion while PSMB 10 was highly expressed mainly in the  
1517 ML2-B7 cell line after IFN- $\gamma$  treatment. This observation seems to correlate in several  
1518 aspects with the results of the co-stimulation experiments with IFN- $\gamma$  pretreated target  
1519 cells as described above. (i) Both cell lines (NB4 and SiG-M5) with the lowest increase  
1520 in PSMB 8 expression after IFN- $\gamma$  pretreatment, showed only marginal effects on  
1521 TCRF5.4-transduced T-cell responses indicating no significant changes in MPO<sub>145</sub> pep-  
1522 tide presentation and points PSMB 8 as a limiting factor for sufficient immunoproteasome  
1523 activity. (ii) HL60 and ML2 with higher PSMB 8 expression also showed the most sub-  
1524 stantial effects in reduction of IFN- $\gamma$  release and cytotoxicity of TCRF5.4-transduced T  
1525 cells after IFN- $\gamma$  pretreatment of these cell lines (Figure 44A, C). In contrast, TCR2.5D6-  
1526 transduced T cells showed nearly no difference in responses after co-stimulation with  
1527 IFN- $\gamma$  pretreatment ML2, HL60, and NB4 cells. Thus, the MPO<sub>145</sub> processing and presen-  
1528 tation machinery is more affected by changes of the PSMB 8-10 subunits than MPO<sub>466</sub> in  
1529 the tested cell line panel.

1530

1531 **Figure 45: mRNA expression of immunoproteasome subunits after IFN- $\gamma$  exposure. The expression**  
 1532 **of PSMB8, 9 and 10 was analyzed by semi-quantitative real-time PCR normalized to the three**  
 1533 **housekeeping genes GAPDH, HMBS, and HPRT1 after IFN- $\gamma$  (200 U/ml) pretreatment for 24h. The**  
 1534 **expression of the cell lines HL60, NB4, SiG-M5, and ML2 was calculated relative to the expression**  
 1535 **of the Jurkat76 cell line (JK76).**

### 1536 3.5.2 Determination of MPO-peptide levels by LC-MS/MS

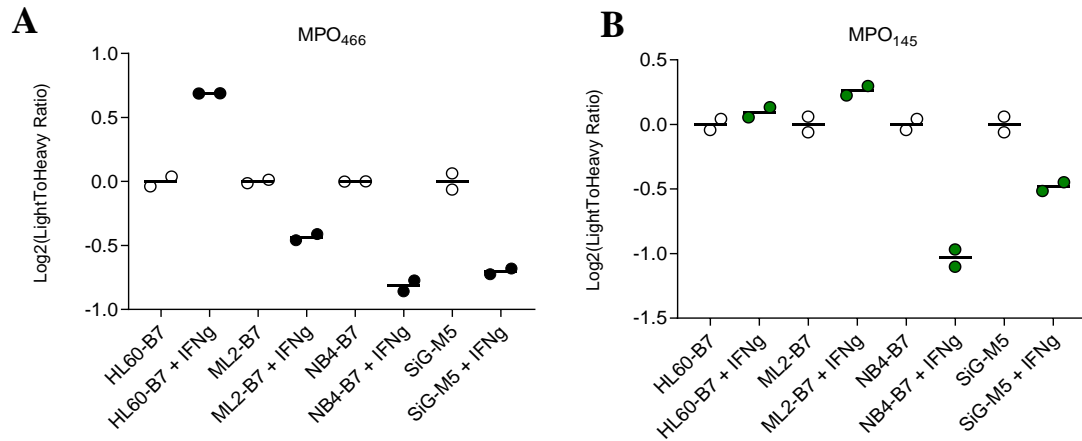

1537 The relative quantification of MPO-peptide intensities presented on the surface of the  
 1538 cells by mass spectrometry was done in collaboration with Matteo Pecoraro from the Max  
 1539 Planck Institute for Biochemistry. The results indicate a substantial higher intensity of  
 1540 MPO<sub>466</sub> on the surface of each AML-cell line compared to MPO<sub>145</sub> (Figure 46). Within  
 1541 the MPO<sub>466</sub> panel, the cell line NB4-B7 displayed the highest MPO<sub>466</sub> intensity followed  
 1542 by ML2-B7, HL60-B7 and SiG-M5. For MPO<sub>145</sub>, the cell lines NB4-B7 and ML2-B7 are  
 1543 similar in their peptide intensity levels followed by HL60-B7 and SiG-M5. Although the  
 1544 detectable levels of surface presented MPO<sub>466</sub> and MPO<sub>145</sub> seems to differ substantially  
 1545 and imply much higher MPO<sub>466</sub> presentation on the surface of all cell lines compared to  
 1546 MPO<sub>145</sub>, it is important to point out that both peptides are biochemically very different.  
 1547 These differences, however, led also to different recoveries of the peptides during the MS  
 1548 measurements. Thus, it needs to be considered that a direct comparison of both peptides  
 1549 might not be adequate.

1550

1551 **Figure 46: Intensity distribution of MPO<sub>145</sub> and MPO<sub>466</sub> on the surface of AML cell lines. The occur-**  
1552 **rences of logarithmic intensities of the MPO<sub>145</sub>- (green) and MPO<sub>466</sub>-peptides (black) on the surface**  
1553 **of the NB4-B7, ML2-B7, HL60-B7, and SiG-M5 cell lines. The detection of the MPO-peptides was**  
1554 **done using heavy labeled Leucine counterparts as controls. The mean of duplicates is shown for one**  
1555 **representative measurement out of two (n = 2). Adapted from [102].**

1556 In a second run, the experiment was repeated with the IFN- $\gamma$  pretreated AML-cell line  
1557 panel. The results were compared to the untreated controls separately for both MPO-pep-  
1558 tides. Except for the HL60-B7 cell line with increased MPO<sub>466</sub> surface intensities, the  
1559 intensities decreased for all the other cell lines ML2-B7, NB4-B7 and SiG-M5 after the  
1560 IFN- $\gamma$  pretreatment (Figure 47A). The intensities for the MPO<sub>145</sub>-peptide were slightly  
1561 elevated in HL60-B7 and ML2-B7 after the IFN- $\gamma$  pretreatment while a decrease was  
1562 observed for NB4-B7 and SiG-M5 (Figure 47B). The IFN- $\gamma$  pretreatment results showed  
1563 a distinct effect of IFN- $\gamma$  on the peptide presentation machinery of the AML-cell lines.  
1564 Partially the results are ambiguous if dragged on the observations made for the IFN- $\gamma$   
1565 pretreatment co-cultivation experiments (Figure 44). As an example, the ML2-B7 cell  
1566 line was hardly detected by TCRF5.4-transduced T cells after IFN- $\gamma$  pretreatment (Figure  
1567 44A) although higher MPO<sub>145</sub> intensity levels have been detected by mass spectrometry  
1568 on the surface of the cells. Taken together, the outcome of the examined IFN- $\gamma$  treatment  
1569 experiment remain controversial and the observed results in-vitro could not be conclu-  
1570 sively explained by mass spectrometry.

1571

1572 **Figure 47: MPO-peptide surface intensities after IFN- $\gamma$  pretreatment of AML cell lines. The occur-**  
 1573 **rences of logarithmic intensities of the MPO<sub>466</sub>- (A) and MPO<sub>145</sub>-peptides (B) on the surface of the**  
 1574 **NB4-B7, ML2-B7, HL60-B7, and SiG-M5 cell lines with (closed circles) or without (open circles) IFN-**  
 1575  **$\gamma$  pretreatment (200 U/ml) for 24h. Values of cell lines without IFN- $\gamma$  pretreatment were set as a**  
 1576 **baseline to display the ratio of peptide intensities for IFN- $\gamma$  treated samples. Results for the MPO<sub>466</sub>**  
 1577 **peptide are shown in (A), for the MPO<sub>145</sub>-peptide in (B), respectively. The detection of the MPO-**  
 1578 **peptides was done using heavy labeled Leucine counterparts as controls. The mean is shown for du-**  
 1579 **plicates of one representative measurement (n = 2).**

1580 3.5.3 Prolonged peptide variants of MPO<sub>145</sub>

1581 MHC-peptide binding prediction tools using peptide-sequence based algorithms are  
 1582 mostly trained for nonameric peptides on MHC-I alleles. The same applies to the HLA-  
 1583 B7 allele implemented in the NetMHC database. To be sure that no nonameric version of  
 1584 the MPO<sub>145</sub>-peptide (octamer) is responsible for the observed immune responses of  
 1585 TCRF5.4-transduced T cells, the nonameric versions LTPAQLNVL (MPO<sub>2</sub>+L1) and  
 1586 TPAQLNVLS (MPO<sub>2</sub>+S9) were synthesized (Genscript) and tested in peptide pulsing  
 1587 experiments using HLA-B7 transgenic KG-1a cells (Figure 48).

1588 No IFN- $\gamma$  release of TCRF5.4-transduced T cells could be observed for the MPO<sub>2</sub>+S9  
 1589 variant. However, the variant MPO<sub>2</sub>+L1 showed nearly the same IFN- $\gamma$  release of  
 1590 TCRF5.4-transduced T cells as shown for the control peptide MPO<sub>145</sub>.

1591

1592 **Figure 48: T-cell responses against nonameric MPO<sub>145</sub>-peptide variants. IFN- $\gamma$  release of TCRF5.4-**  
 1593 **transduced T cells measured by IFN- $\gamma$  ELISA after co-incubation with either MPO<sub>145</sub>- (wt),**  
 1594 **MPO<sub>145</sub>+L1- or MPO<sub>145</sub>+S9-pulsed LCL cells with endogenous HLA-B7 expression for 20h. Not**  
 1595 **transduced T cells and T cells without target cell incubation served as controls. The mean  $\pm$  s.d. of**  
 1596 **triplicates is shown for n=2 [102].**

1597 Although it cannot be excluded that HLA-B7-bound MPO<sub>2</sub>+L1 is a naturally presented  
 1598 T-cell epitope, this peptide was not detected by immunopeptidomics so far (see chapter  
 1599 3.1). Furthermore, MPO<sub>2</sub>+L1 peptide modeling revealed that the additional N-terminal  
 1600 leucine might have no positive contribution to the HLA-B7 complex binding (see chapter  
 1601 3.5.6).

#### 1602 3.5.4 UV-mediated peptide exchange

1603 With the technique of the UV-mediated peptide exchange, the potential of the MPO-pep-  
 1604 tides was assessed to rescue the HLA-B7 complex once the UV-sensitive placeholder  
 1605 peptide had been cleaved by UV-light. Figure 49A shows the results of the experiments  
 1606 and revealed that MPO<sub>466</sub> was the peptide with the lowest  $V_{50}$  value (-5.204) compared  
 1607 to the MPO<sub>145</sub>- (-4.610) and MPO<sub>2</sub>+L1 (-4.143) peptides. Thus, a significant reduced half-  
 1608 maximal MPO<sub>466</sub>-peptide concentration was necessary to rescue the HLA-B7 complexes  
 1609 compared to MPO<sub>145</sub> (Figure 49B). This result indicates either a stronger HLA-binding  
 1610 affinity, HLA-stabilizing potential or faster complex association ( $k_{on}$ -rate) of MPO<sub>466</sub>  
 1611 peptide to the HLA-B7 molecule compared to MPO<sub>145</sub>.

1612

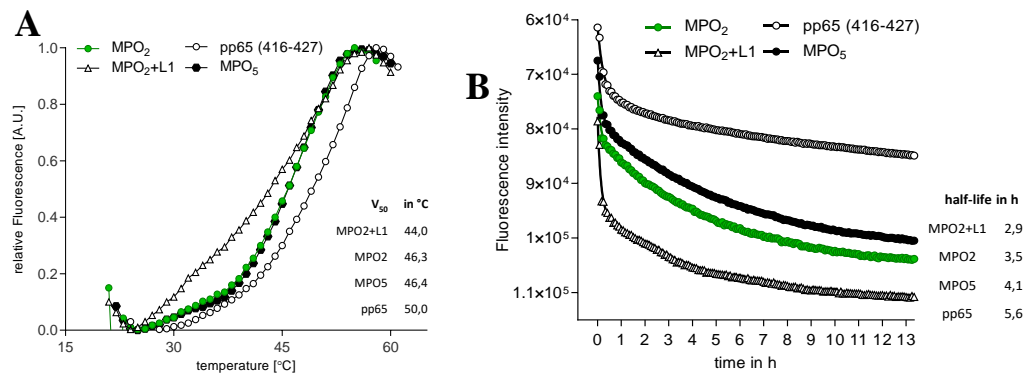

1613 **Figure 49: p-MHC stability of MPO<sub>145</sub> and MPO<sub>466</sub> HLA-molecules after UV-mediated peptide**  
 1614 **exchange. (A) Representative results of UV-mediated peptide exchanges of HLA-B7 monomers for**  
 1615 **the peptides (l.t.r.) MPO<sub>466</sub>, MPO<sub>145</sub>, and MPO<sub>145</sub>+L1. MPO-peptide exchange efficiency was**  
 1616 **measured by beta-2-microglobulin (B2M)-ELISA for graded amounts of peptides followed by**  
 1617 **calculation of V<sub>50</sub> values using Boltzmann curve fitting algorithms of GraphPad Prism 8. The mean**  
 1618 **± s.d of triplicates is shown for each peptide. (B) Pooled results of V<sub>50</sub> values for MPO<sub>466</sub> n=4, MPO<sub>145</sub>**  
 1619 **n=4 and MPO<sub>145</sub>+L1 n=3. The Mann-Whitney test was used for statistical analysis: \*p<0.05 [102].**

### 1620 3.5.5 Differential Scanning Fluorimetry of MPO-peptides

1621 For further analysis of p-MHC complex stability, the differential scanning fluorimetry  
 1622 (thermal shift assay) method was used. This technique uses the property of a protein to  
 1623 denature at a specific temperature in dependence of its stability. The more stable the com-  
 1624 plex is, the higher temperature it can withstand. In addition, a stable protein denatures  
 1625 later than an unstable protein at constant temperatures. For the monitoring of denaturation  
 1626 SYPRO Orange was used. This dye attaches to hydrophobic amino acid residues that  
 1627 become accessible during denaturation and directly correlates with the degree of denatur-  
 1628 ation.

1629 Interestingly, the two HLA-peptide complexes MPO<sub>466</sub> and MPO<sub>145</sub> displayed nearly the  
 1630 same temperatures necessary to denature ½ of all p-MHC complexes at around 46°C (Fig-  
 1631 ure 50A). The high-affinity CMV peptide-pp65<sub>(416-427)</sub>-HLA-B7 complex was used as a  
 1632 control and showed the highest p-MHC complex stability with a half-maximal tempera-  
 1633 ture of 50°C. In contrast, the MPO<sub>2</sub>+L1 complex denatured at a half-maximal temperature  
 1634 of 44°C and displayed the weakest p-MHC stability.

1635 In a second experiment, the temperature was adjusted constantly to 37°C, and the dena-  
 1636 turation of the p-MHC complexes was monitored over time (Figure 50B). Again, the  
 1637 pp65-MHC complex showed the most robust complex stability with a half-life of 5.6h  
 1638 and the MPO<sub>2</sub>+L1-MHC complex the weakest complex stability with a half-life of 2.9 h.  
 1639 This time, the MPO<sub>145</sub>- and MPO<sub>466</sub>-MHC complexes clearly showed differences in com-  
 1640 plex stability. With a half-life of 4.1 h, the MPO<sub>466</sub> complex was longer stable than the  
 1641 MPO<sub>145</sub> complex (3.5 h). To conclude, the results of thermal shift assays provide the fol-  
 1642 lowing order of MPO p-MHC complex stabilities: MPO<sub>466</sub> > MPO<sub>145</sub> > MPO<sub>2</sub>+L1.

1643

1644 **Figure 50: Thermal shift assay of MPO<sub>466</sub>-, MPO<sub>145</sub>- and MPO<sub>145</sub>+L1- UV-exchanged HLA-B7**  
 1645 **monomers. (A) HLA-B7 monomer denaturation was monitored during continuous heating starting**  
 1646 **from 21°C to 95°C simultaneously for all three MPO-MHC complexes compared to the pp65-MHC**  
 1647 **complex (pp65 = CMV-derived and also HLA-B7 restricted). The half-maximal denaturation ( $V_{50}$  in**  
 1648 **°C) was calculated by Boltzmann fitting algorithms using GraphPad Prism 8. (B) Stability of MPO-**  
 1649 **peptide-HLA-B7 monomers over time at constant temperature of 37°C compared to the pp65-HLA-**  
 1650 **B7 complex. The half-life of each peptide-MHC complexes was calculated by GraphPad Prism 8**  
 1651 **using the two-phase exponential decay algorithm selecting the slowest constant rates. The means of**  
 1652 **quadruplicates are shown for both figures (n=2). The increasing fluorescence during denaturation or**  
 1653 **decay of the peptide-HLA complexes was monitored by SYPRO orange. Adapted from [102].**

1654 3.5.6 Characterization of MPO-MHC complexes by structural modeling

1655 For more insights into the binding properties, especially on a structural basis, the MPO-  
 1656 peptide complexes were modeled and underwent molecular dynamic simulations per-  
 1657 formed by Manuel Glaser and Iris Antes from the Center for Integrated Protein Science  
 1658 at the Technical University Munich in Freising, Germany. Detailed results can be found

1659 in the PhD-thesis related publication [102]. In brief, molecular dynamic simulations re-  
1660 vealed a much higher conformational stability of MPO<sub>466</sub> compared to the MPO<sub>145</sub>-pep-  
1661 tide with higher flexibility within the MHC-binding cleft. The results support the weaker  
1662 MPO<sub>145</sub> HLA-stability observed in the UV-mediated peptide exchange (see chapter 3.5.4)  
1663 and differential scanning fluorimetry assays (see chapter 3.5.5). Subsequent comparisons  
1664 to prediction results using the NetMHC4.0- and the SYFPEITH platforms showed excel-  
1665 lent correlations and verified the higher HLA-affinity of MPO<sub>466</sub> compared to MPO<sub>145</sub>  
1666 (Table 27). Conclusively, the weaker HLA-binding affinity of the MPO<sub>145</sub>-peptide lowers  
1667 the cell surface presentation compared to MPO<sub>466</sub> (see chapter 3.5.2) because of more  
1668 competitive MPO<sub>466</sub>-peptide loading of HLA-B7 molecules. Furthermore, alanine and  
1669 threonine variants of the MPO<sub>145</sub>- and MPO<sub>466</sub>-peptides were modeled and their in-silico  
1670 p-MHC flexibility was compared to the experimental results of amino acid substitution  
1671 assays (see chapter 3.2.7). Regarding this, the most important insight was a correlation  
1672 between higher HLA-B7 binding affinities of single MPO<sub>466</sub> variants and increased IFN-  
1673  $\gamma$  release of TCR2.5D6-transduced T cells in co-stimulation experiments. Taken together,  
1674 the structural modeling of the MPO-HLA-complexes strongly support our experimental  
1675 in-vitro data of MPO<sub>466</sub> superiority regarding HLA-binding affinity and quality compared  
1676 to the MPO<sub>145</sub>-peptide.

## 1677 4 Discussion

### 1678 4.1 The selection of methods for TCR-p-MHC characterization

#### 1679 4.1.1 Only a small proportion of selected target antigens leads to promising TCR

1680 In this work, MHC-mismatched allorestricted T-cell responses against diverse MPO-de-  
1681 rived peptide ligands were investigated that had been identified by immunopeptidomics  
1682 of tumor samples derived from patients with MPN [43]. The primary goal was to establish  
1683 a TCR library specific for MPO-peptides to treat these diseases in an advanced stage with  
1684 TCR-transgenic T cells. Such a therapy may be used in the context of allogeneic stem cell  
1685 transplantation [108, 109] in a haplo- or sHLAm setting as well as alternatively within a  
1686 conditioning regimen. The promising potential of adoptive transfers of immunoreceptor  
1687 transgenic T cells, has been shown in the case of chimeric antigen receptors targeting B-  
1688 cell malignancies [110, 111] or in the case of TCRs targeting melanomas [5]. However,  
1689 only a small proportion of experimentally identified immunoreceptors enters the stage of  
1690 clinical translation. In case of the six different MPO-peptides used for T-cell stimulation,  
1691 only one novel allorestricted TCR (TCRF5.4) with high specificity for the HLA-B7-re-  
1692 stricted MPO-derived peptide MPO<sub>145</sub> could be identified. All other TCR candidates were  
1693 excluded as potential candidates for clinical translation after meeting different kinds of  
1694 stopping criteria indicating major hurdles for clinical translation. Major hurdles were for  
1695 instance the lack of isolation and expansion of specific T-cell clones targeting MPO<sub>266</sub>,  
1696 MPO<sub>357</sub> and MPO<sub>67</sub>, failure in TCR expression after retroviral transfer of a TCR construct  
1697 specific for MPO<sub>603</sub> and peptide-independent recognition of target cells after TCR trans-  
1698 fer in case of MPO<sub>368</sub>. The insufficient surface expression or missing peptide specificity  
1699 might be related to the composition of the TCR itself as it was shown before for other  
1700 TCRs [112].

1701 For the successful isolation and expansion of MPO<sub>145</sub>-specific T cells within sHLAm-  
1702 (HLA-B7) stimulated T-cell pools, the combination of a general depleting step of CD137<sup>+</sup>  
1703 HLA-B7 alloreactive T-cells [113] followed by multimer-based sorting [114] was suc-  
1704 cessfully applied. Without exception, all expanded T-cell clones after isolation showed  
1705 distinct MPO<sub>145</sub> specificity and shared the same sequences for the TCR alpha and beta  
1706 chains.

1707 4.1.2 Does a well-defined selection process for TCR identification exist?

1708 One aim of this work was to define key in-vitro or in-silico characteristics for the selection  
1709 of MHC-binding peptides and respective TCRs to facilitate future screening approaches  
1710 of allorestricted TCRs to reduce or even to skip laborious in-vivo experiments. For that  
1711 reason, the newly identified TCRF5.4 was compared to the previously characterized  
1712 TCR2.5D6 [43] in side by side experiments in order to reveal both shared characteristics  
1713 and differences. Therefore, the allorestricted TCR2.5D6 was ideal for in-depth analyses  
1714 since this TCR shares the same HLA-B7 restriction element as well as the same target  
1715 protein MPO with TCRF5.4. The choice of most in-vitro experiments was aligned to lit-  
1716 erature that reflects a connection between strong T-cell responses and anti-tumor capacity  
1717 in-vivo [27, 80-82, 84-86, 115]. Consequently, for both TCRs, the expression, functional  
1718 avidity, dissociation from the p-MHC complex ( $k_{\text{off-rate}}$ ), cytokine release after stimula-  
1719 tion, cytotoxicity against cell lines as well as cross-reactivity in-vitro was analyzed. Ad-  
1720 ditionally, T-cell responses against target cell lines were analyzed that have been pre-  
1721 treated with different concentrations of IFN- $\gamma$  to mimic the release of IFN- $\gamma$  by T cells  
1722 during T-cell / target cell engagement in immune responses [116].

1723 Among all these methods, functional differences of both TCRs were limited and mainly  
1724 observed in TCR expression, quality and quantity of cytokine release as well as cross-

1725 reactivity. In contrast, no significant differences were seen for target cell lysis, dissocia-  
1726 tion time of TCRs from p-MHC complex and functional avidity. Thus, these functional  
1727 analyses failed to describe the proposed correlation of in-vivo outcome and strength of  
1728 TCRs. Similar applies to TCR-p-MHC off-rates. Although reported as a critical factor, it  
1729 failed to predict the different qualities of TCRF5.4- and TCR2.5D6-related immune re-  
1730 sponses [117] after adoptive transfer of T cells [81] into the chosen NB4 in-vivo model.  
1731 The same applies to the functional avidity of TCRs towards the cognate MHC-peptide  
1732 complexes which is reported to be a preferential selection criterion [84]. Specific features  
1733 of MHC-mismatched TCRs could explain the lack of significant differences between both  
1734 TCRs in  $k_{\text{off}}$ -rate and functional avidity. As reported elsewhere, allogeneic TCRs might  
1735 have alternative binding features to the mismatched MHC involving CDR1 and CDR2  
1736 domains [118] potentially compensating for lower p-MHC as well as TCR-p-MHC affin-  
1737 ity. Thus, functional avidity, as well as  $k_{\text{off}}$ -rate analyses, seem not to be predictive to  
1738 identify allorestricted TCRs with high potential for clinical translation.

1739

1740 Although both TCRs are codon optimized [98], murinized [97] and the translation of the  
1741 TCR $\alpha$ - and  $\beta$ -chains was improved by bi-cistronic vectors using a 2A self-cleaving ele-  
1742 ment [96] with insertion of an additional cysteine bridge similar to a previous report [119],  
1743 the TCRF5.4 showed a reduced surface expression and MFI in transgenic T cells. It would  
1744 be conceivable for further analyzes to harmonize the TCR expression between both TCRs  
1745 in order to ensure better comparability of results that depend on TCR expression levels.  
1746 To achieve this, micro RNAs or DNA cleaving nucleases can be used to silence the ex-  
1747 pression of the endogenous TCRs [120] or intersect the sequence within a TCR gene locus  
1748 [121], respectively. State of the art approach uses the CRISPR-Cas technology to do both,  
1749 disruption of endogenous TCR expression and simultaneous insertion of the transgenic

1750 TCR or CAR sequence into the TCR gene locus [48, 49]. However, although TCR ex-  
1751 pression might be relevant, as also shown for the MPO<sub>603</sub>-specific HLA-A2-TCR within  
1752 this work with insufficient surface presentation, TCRF5.4 indicates that minor differences  
1753 of generally well-expressed TCRs may not be critical in some cases. Additionally, pre-  
1754 cisely because the expression of both TCRs have not been additionally manipulated, it  
1755 was possible to examine TCR- and recipient cell-related influences on TCR surface ex-  
1756 pression levels, as they are present in clinical application. TCRF5.4-transduced T cells  
1757 were competitive in cytotoxicity in-vitro which may, however, not represent the most  
1758 sensitive test for strong T-cell responses as previously described [122]. The results pre-  
1759 sented here also indicate that TCRF5.4 might have a higher functional avidity compared  
1760 to TCR2.5D6 because of similar performance in these experiments despite lower TCR  
1761 presentation quality and quantity as determined by flow cytometry. In contrast, the  
1762 TCRF5.4 was inferior concerning qualitative and quantitative cytokine secretion in com-  
1763 parison to TCR2.5D6-transduced T cells possibly explaining inferiority in tumor rejection  
1764 in-vivo [123-125]. However, considering the high functional avidity of the TCR, com-  
1765 pensation of inferior in-vitro cytokine secretion of TCRF5.4-transgenic T cells after co-  
1766 culture with peptide-pulsed targets indicates either inferior MPO<sub>145</sub> peptide presentation  
1767 or reduced p-MHC potency.

1768

1769 Regarding the differences in peptide presentation, MS-based results may support an infe-  
1770 rior MHC presentation of MPO<sub>145</sub> compared to MPO<sub>466</sub>. Unfortunately, it cannot be ex-  
1771 cluded that the reduced detection of MPO<sub>145</sub> using the immunopeptidomic approach could  
1772 also rely on its biochemical nature possibly not optimal accessible for MS analyses. The  
1773 two leucine and the valine within the MPO<sub>145</sub>-peptide sequence make it very hydrophobic  
1774 leading to fractions with high high-performance liquid chromatography (HPLC) retention  
1775 times of often lower quality. Additionally, the absence of typical ionizable amino acids

1776 in the MPO<sub>145</sub> sequence prevents an efficient peptide ionization important for high quality  
1777 mass spectra. In contrast, although MPO<sub>466</sub> also contains a hydrophobic leucine, it has  
1778 two compensating hydrophilic arginines, one of them very close to the C-terminal end,  
1779 making it nearly ideal for MS analysis.

1780 Other efforts to confirm the differences in MPO<sub>145</sub> and MPO<sub>466</sub> peptide presentation lev-  
1781 els could not be applied for different reasons. It has been tried to assess the MFI of fluo-  
1782 rescently labeled MPO-peptides pulsed on HLA-B7 transgenic target cells. However, the  
1783 fluorescent labels themselves diminished proper peptide binding to the HLA-molecules  
1784 as confirmed by control assays testing for functional recognition of respective target cells  
1785 with labelled peptides by both TCR constructs.

1786 Regarding p-MHC potency, a reduced MPO<sub>145</sub>-MHC stability was observed in a UV ex-  
1787 change assays compared to MPO<sub>466</sub>-MHC indicating overall lower p-MHC affinity. The  
1788 lower MPO<sub>145</sub>-MHC stability might significantly contribute to the experimental inferior  
1789 tumor rejection of TCRF5.4. Indeed, our observations of improved in-vivo outcome for  
1790 T cells with specificity for the peptide MPO<sub>466</sub> with higher p-MHC stability and affinity  
1791 are in line with reports about tumor reactive TCRs in the autologous MHC environment  
1792 [27]. Furthermore, the quality of cytokine secretion [86, 122] was confirmed to be most  
1793 sensitive in detecting potent in-vitro TCR responses also for allorestricted TCRs. Unfor-  
1794 tunately, a direct comparison of our experimentally determined HLA-stability values with  
1795 HLA-affinities of peptides presented by Engels et al., assessed by radiolabeled competi-  
1796 tive peptide assays, was not possible due to different assays formats. Net-MHC 4.0 algo-  
1797 rithms [68, 103] for affinity prediction of both MPO-peptides revealed predicted HLA-  
1798 binding affinities of 36.75 nM for MPO<sub>466</sub> and 305 nM for MPO<sub>145</sub>. Therefore, values for  
1799 both peptides lie above the proposed threshold of 10 nM peptide affinity necessary for  
1800 relapse-free tumor eradication in-vivo [27]. For clear comparison, either the MPO-pep-  
1801 tides need to be analyzed by the same competitive radiolabeled peptide approach [126]

1802 as performed by Engels and colleagues or their peptides need to be analyzed by the UV-  
1803 exchange approach. Alternatively, novel and cutting-edge technologies as for instance  
1804 thermophoresis, measuring binding affinities of small molecules to protein complexes,  
1805 might be a third possibility to precisely determine binding affinities of p-MHCs once  
1806 adapted to this purpose [127].

1807 Apart from the missing direct comparability of the MPO-peptides to peptides used in  
1808 other studies, the presented dependency of peptide-binding quality and individual T-cell  
1809 activity positively correlates as reported previously [128].

1810 Another feature that should be investigated in subsequent work is TCR-p-MHC affinity  
1811 determination. While we extensively investigated the dissociation of the TCR-p-MHC  
1812 complexes, the  $k_{on}$ -rates of TCRs might be another suitable parameter for the screening  
1813 to identify appropriate TCRs.

1814 The TCR-affinity is reported to be highly relevant for adequate triggering of intracellular  
1815 immune responses [129]. However, recent models also revealed that low affinity values,  
1816 meaning longer  $k_{on}$ -rates, might induce even higher T-cell responses compared to TCRs  
1817 with shorter TCR-p-MHC association times [79]. Therefore, similar to our TCR dissoci-  
1818 ation analyzes, the sole consideration of either  $k_{on}$ - or  $k_{off}$ -rate for the prediction of T-cell  
1819 responses may not be sufficient [79]. In addition, there is not necessarily a positive cor-  
1820 relation between affinity prediction and experimental outcome [130, 131]. Therefore, in  
1821 addition to prediction, experimental validation seems to be indispensable.

#### 1822 4.1.3 In-vivo experiments revealed substantial differences in tumor rejection

1823 As peptide presentation on the surface of tumor cells was identified as a critical factor  
1824 and as the TCRs target different peptides, an in-vivo test model contrary to Engels et al.,  
1825 2013 was chosen for several reasons. There, the impact of different antigen expression

1826 levels on single TCR performances was estimated by evaluating eGFP expression cou-  
1827 pled to the whole antigen [27]. Such comparison, however, does not consider downstream  
1828 antigen processing and peptide presentation. This limitation would not be appropriate for  
1829 the analysis of different TCRs targeting different p-MHC molecules. Although the MPO  
1830 antigen expression in this work was every time identically for both TCR conditions as the  
1831 targeted tumor cell lines were the same, the MPO-derived target peptide presentation for  
1832 MPO<sub>145</sub> and MPO<sub>466</sub> was fundamentally different. Even approaches using MPO mini-  
1833 gene transduced tumor cell lines would not have led to comparable surface presentation  
1834 levels between both MPO-peptides. As a fundamental reason for this, endogenous peptide  
1835 processing- and presentation machinery leads to different amounts of presented peptides  
1836 conditioned by the peptide quality itself. In contrast, using the described NB4 tumor  
1837 model with different presentation levels of both MPO-peptides as indicated in the respec-  
1838 tive analysis mimics a close to the clinic's situation where peptide presentation levels are  
1839 also not harmonized. Furthermore, the NB4 cell line with transgenic HLA-B7 expression  
1840 was selected because this cell line elicited almost equal in-vitro functionality in cytokine  
1841 release and cytotoxicity before and after IFN- $\gamma$  pre-stimulation of both TCR-transgenic  
1842 T-cell populations. This characteristic is important to estimate the possible loop impact  
1843 of IFN- $\gamma$  release by the adoptively transferred T-cells on the peptide processing and  
1844 presentation of both MPO-peptides in NB4-derived tumors. In this regard, T-cell re-  
1845 sponses against different IFN- $\gamma$  pretreated target cell lines with endogenous MPO expres-  
1846 sion were analyzed. Additionally, these target cell lines were analyzed for different im-  
1847 munoproteasome subunits. However, a single correlation between proteasome subunit  
1848 beta (PSMB) 8, 9 and 10 expression in target cells and alterations of T-cell responses  
1849 could not be observed. One hint might be the inferior PSMB 9 expression in NB4 cells  
1850 compared to the other AML-cell lines that might be not enough to disrupt the MPO<sub>145</sub>

1851 processing machinery even at high IFN- $\gamma$  conditions. Here, further experiments would be  
1852 necessary to clarify this causality.

1853 As TCR-transgenic T-cell conditions from a donor and transduction with comparable  
1854 transduction efficacies as well as TCR-density surface expression for both TCR were se-  
1855 lected for the long-term in-vivo study, the superior outcome of the TCR2.5D6 group was  
1856 initially unexpected. Thereby, both TCRs differed sharply in their tumor rejection capac-  
1857 ity. Mice treated with TCR2.5D6-transduced T cells showed significantly longer survival  
1858 compared to those treated with TCRF5.4-transduced T cells. Of note, all mice in the group  
1859 of TCR2.5D6 also relapsed after apparent tumor eradication. However, tumor escape  
1860 mechanisms were different in both groups. Whereas tumors in mice treated with  
1861 TCR2.5D6-transduced T cells lacked HLA-B7 and lost all TCR-transgenic T cells,  
1862 TCRF5.4-transgenic T cells could be detected in all examined tissues except in the still  
1863 HLA-B7-expressing tumors. Loss of HLA-B7 indicates an intense immunogenic pressure  
1864 by strong tumor reactivity and resembles observations made with CD19-CAR T cells  
1865 [132] although this may happen more easily in case of an HLA-B7 transgene as present  
1866 in target cells in this model. In contrast, although TCRF5.4-transgenic T cells have well  
1867 engrafted, our experiments indicate that tumor escape relies more on peptide and TCR-  
1868 intrinsic features failing to provide complete tumor eradication. Furthermore, increased  
1869 infiltration of TCRF5.4-T cells into the lung compared to TCR2.5D6-T cells could be  
1870 observed and might be a hint for TCRF5.4-related cross-reactivity. Taken together, our  
1871 findings underline that the most critical differences seen in-vitro, comprising cytokine  
1872 release quality and quantity as well as peptide quality itself, might be key selection criteria  
1873 to identify superior TCR-p-MHC combinations.

## 1874 4.1.4 TCRF5.4 revealed higher cross-reactivity compared to TCR2.5D6

1875 For the identification and isolation of TCRF5.4, the same sHLAm stimulation approach  
1876 was applied as for the TCR2.5D6. However, both TCR differ in their cross-reactivity  
1877 pattern analyzed by a set of typical experiments comprising the screening of randomly  
1878 chosen cognate and non-cognate peptides for HLA-B7 [43], screening of LCL cell lines  
1879 with common HLA [94] and amino acid substitution assays [133]. Here, TCRF5.4 re-  
1880 vealed different TCR-binding motifs in dependence which amino acid, either alanine or  
1881 threonine, was used for the substitution. Although each motif, analyzed separately in  
1882 ScanProsite analyses [92], led to only one different protein containing this specific motif,  
1883 the combined pattern of the alanine- and threonine scan revealed numerous hits. Thus,  
1884 these results indicating very high peptide promiscuity and a higher risk for more unspe-  
1885 cific TCR-binding compared to TCR2.5D6 with a consolidated TCR-binding motif for  
1886 both alanine- and threonine scan. These differences might be explained by a rather HLA-  
1887 focused binding of TCRF5.4 with an only minor contribution of the MPO<sub>145</sub> peptide to a  
1888 stable TCR-binding and a vice versa for TCR2.5D6. It might be precisely this binding  
1889 quality of TCRF5.4 that could explain the observed MPO<sub>145</sub>-peptide independent cross-  
1890 reactivity against HLA-B51 as described previously [118]. Detailed analyses of the  
1891 ScanProsite hits for MPO<sub>145</sub> would make it necessary to apply sequence and structure-  
1892 based in-silico predictions as well as statistical tools to narrow down the hits to a man-  
1893 ageable quantity of potential cross-reactive peptides to be tested in experimental assess-  
1894 ments before further clinical translation of TCRF5.4.

1895 4.1.5 Structure-based p-MHC modeling support key results and might substitute  
1896 laborious peptide screening in future

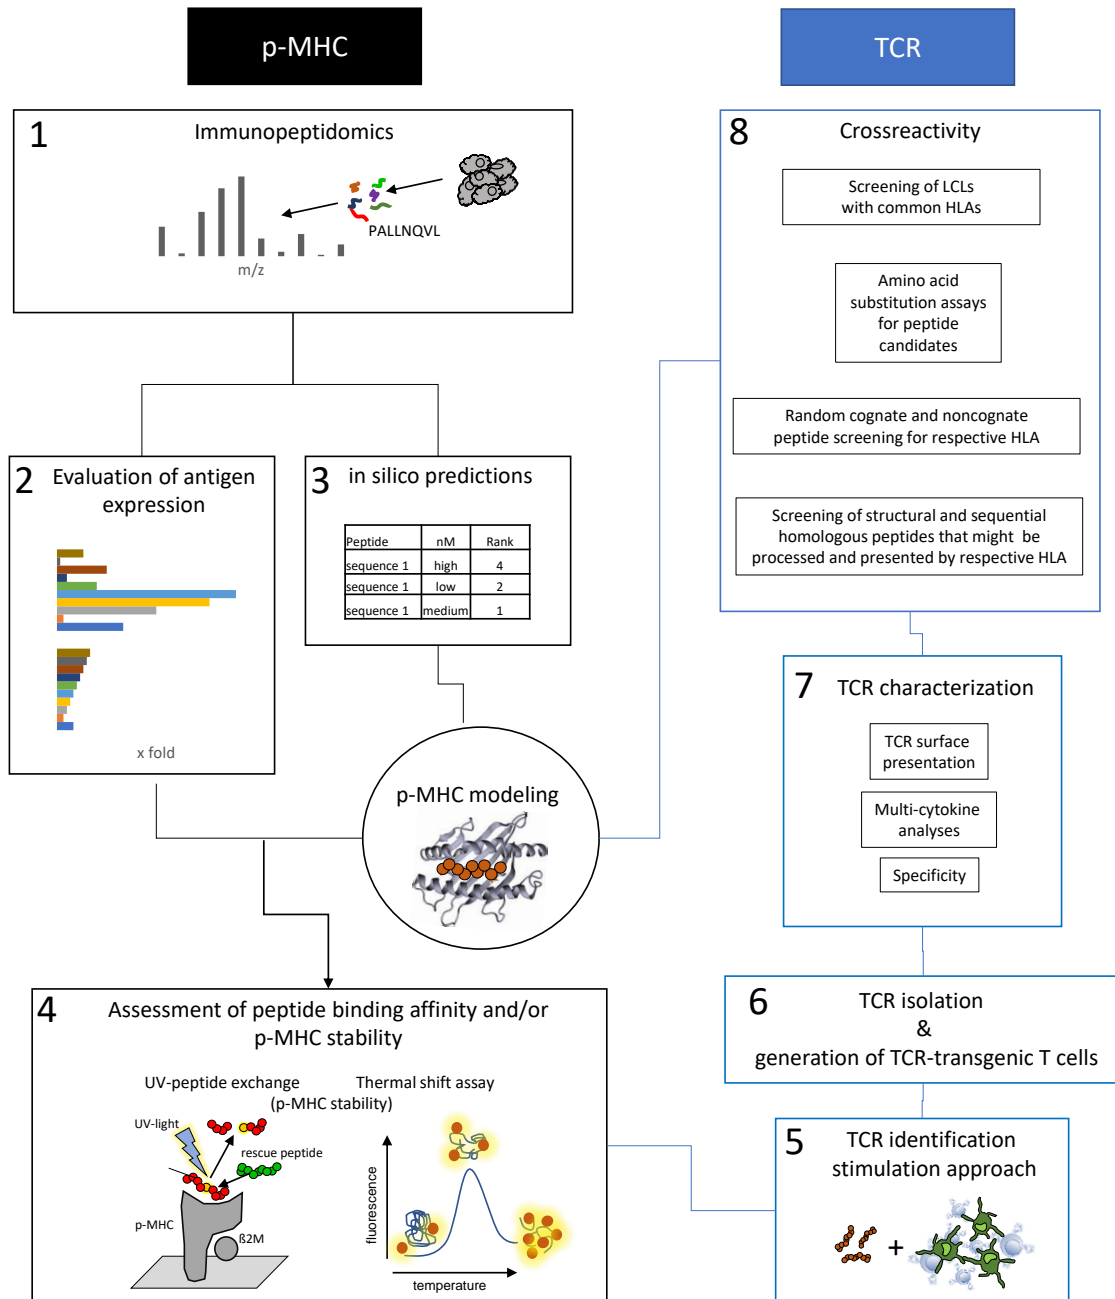

1897 Structure-based modeling and molecular-dynamic simulations done in cooperation with  
1898 the group of Iris Antes for both p-MHC complexes revealed the molecular basis of ex-  
1899 perimental peptide stability results measured by UV exchange assays and give explana-  
1900 tions for the observed TCR-binding motifs derived from the amino acid substitution as-  
1901 says. Furthermore, the results of the structure-based p-MHC modeling are in line with  
1902 sequence-based predictions calculating the p-MHC binding affinity.

1903 Experimentally, MPO<sub>466</sub>-peptide variants (substituted by alanine or threonine at position  
1904 six) induced enhanced IFN- $\gamma$  release of TCR2.5D6-transduced T-cells leading to higher  
1905 T-cell activity because of improved p-MHC binding quality compared to the wildtype  
1906 MPO<sub>466</sub>-peptide. In contrast, the higher in-silico determined peptide flexibility of MPO<sub>145</sub>  
1907 within the MHC-binding cleft seems to allow a more flexible binding of TCRF5.4 as  
1908 observed in the alanine and threonine amino acid substitution assays. Additionally, the  
1909 experimentally observed differences in TCRF5.4-binding motifs for either alanine or  
1910 threonine MPO<sub>145</sub>-peptide variants could be an indication for TCRs with higher risk for  
1911 unspecific binding. Therefore, it is proposed to use several different amino acids for the  
1912 analysis of the TCR-binding motif. Taken together, these observations combined with the  
1913 individual assessed cross-reactive potential of both TCR strongly supports a correlation  
1914 of TCR specificity, peptide flexibility and cross-reactivity. The TCR2.5D6 targeting the  
1915 more stiff peptide of higher affinity, probably leading to the favorable TCR-recognition  
1916 motif, revealed a very promising cross-reactive profile [43]. For TCRF5.4, it seems to be  
1917 exactly the opposite. Here, the peptide is more flexible within the MHC-binding cleft, the  
1918 TCR displayed a complex TCR-binding motif and revealed a higher cross-reactive po-  
1919 tential as observed in our experimental measurements. Consequently, molecular dynamic  
1920 simulations and structure-based p-MHC modeling together with amino acid substitution

1921 experiments in combination with cross-reactivity analyses may be a suitable set of tools  
1922 to identify TCRs with insufficient specificity or risky cross-reactive potential early in the  
1923 TCR characterization workflow.

#### 1924 4.1.6 Conclusion and Outlook

1925 The presented in-depth analyses of p-MHC binding and TCR functionality leads to the  
1926 conclusion that characteristics of cytokine release and p-MHC binding are the most ap-  
1927 propriate features to discriminate time-efficiently between allogeneic TCRs that are suit-  
1928 able for further clinical translation and TCRs that might carry a higher risk of potential  
1929 cross-reactivity or ineffectiveness in clinical applications. Based on our discoveries, we  
1930 propose a curtailed set of methods (Figure 51) for the characterizations of allorestricted  
1931 TCRs that might help researchers to be able to decide early on in TCR screening whether  
1932 a TCR is worth it to go on with or not. Thereby we have taken care of practicability and  
1933 time-efficiency of selected methods in order to empower high-efficacy immunotherapies  
1934 using transgenic TCR with a favorable safety profile. However, further analyses of new  
1935 available TCRs or retrospectively of already well characterized TCRs are urgently needed  
1936 to proof our concept for TCRs identified in the MHC-mismatched allogeneic repertoire.

## 2309 Acknowledgments

2310 An erster Stelle möchte ich Prof. Dr. med. Angela Krackhardt für die ausgezeichnete Be-  
2311 treuung und Ihre großartige Unterstützung während dieser aufregenden Zeit danken. Be-  
2312 sonders auch dafür, dass Sie neben Ihrer klinischen Arbeit immer Zeit gefunden hat mir  
2313 mit inspirierendem Rat und Tat zur Seite zu stehen.

2314 Danke auch an Prof. Dr. med. Christian Peschel für die Bereitstellung der notwendigen  
2315 Infrastruktur innerhalb der III. Medizinischen Klinik.

2316 Weiteren Dank möchte ich auch Prof. Iris Antes und Dr. Manuel Glaser für die großartige  
2317 Zusammenarbeit, besonders am Ende des Projects, aussprechen. Zahlreiche intensive  
2318 Treffen, Anregungen und Diskussionen haben die exzellente Qualität der Modelling Er-  
2319 gebnisse erst möglich gemacht.

2320 Großer Dank gilt auch Prof. Dr. med. Dirk Busch und seinem Labor. Hier danke ich be-  
2321 sonders Manuel Effenberger für die Zusammenarbeit und die zahlreichen wissenschaftli-  
2322 chen, aber auch persönlichen Gespräche.

2323 Danken möchte ich auch Matteo Pecoraro vom Max-Planck-Institut für Biochemie für  
2324 die angenehme Zusammenarbeit und die Durchführung der Massenspektrometrie und Jo-  
2325 sef Mautner vom Helmholtz-Zentrum für das freundliche Mentoring.

2326 Vielen Dank auch an Nicole Abbrederis und Almut Barden für die freundliche Unterstüt-  
2327 zung und das Beantworten zahlloser Fragen rund um das PhD-Programm.

2328 Ein ganz herzlicher Dank geht an das gesamte Team der AG Krackhardt. Besonders  
2329 möchte ich Stephanie Rämisch, Richard Klar, Sabine Mall und Eva Bräunlein für Ihre  
2330 wertvolle Unterstützung und Freundschaft danken.

2331 Abschließend möchte ich meiner Familie für die unendliche Geduld und Rücksichtnahme  
2332 während der Promotion danken und dafür, dass Sie immer für mich da waren.
